Product Monograph

Pr. TARO- CARBAMAZEPINE Tablets 200 mg
(Carbamazepine Tablets, Taro Standard)

Pr. TARO- CARBAMAZEPINE Chewable Tablets 100 mg and 200 mg
(Carbamazepine Chewable Tablets)

Pr. TARO- CARBAMAZEPINE CR Tablets 200 mg and 400 mg
(Carbamazepine Extended-Release Tablets, Taro Standard)

Pr. TARO- CARBAMAZEPINE Suspension 100 mg/5 mL
(Carbamazepine Oral Suspension, USP)

Anticonvulsant

For Symptomatic Relief of Trigeminal Neuralgia

Antimanic

Taro Pharmaceuticals Inc.

INDICATIONS AND CLINICAL USE

Epilepsy:
Adults (>18 Years of age)
TARO-CARBAMAZEPINE (carbamazepine) is indicated for use as an anticonvulsant drug either alone or in combination with other anticonvulsant drugs.

Carbamazepine is not effective in controlling absence; myoclonic or atonic seizures, and does not prevent the generalization of epileptic discharge. Moreover, exacerbation of seizures may occasionally occur in patients with atypical absences.

Pediatrics (> 6 years of age):
TARO-CARBAMAZEPINE is indicated for use as an anticonvulsant drug either alone or in combination with other anticonvulsant drugs (see DOSAGE and ADMINISTRATION, Recommended Dose and Dosage Adjustment, Use in Epilepsy, Adults and Children Over 12 Years of Age and Children 6-12 Years of Age).

Trigeminal Neuralgia:
Adults (>18 Years of age)
TARO-CARBAMAZEPINE is indicated for the symptomatic relief of pain of trigeminal neuralgia only during periods of exacerbation of true or primary trigeminal neuralgia (tic douloureux). It should not be used preventively during periods of remission. In some patients,
Carbamazepine has relieved glossopharyngeal neuralgia. For patients who fail to respond to TARO-CARBAMAZEPINE, or who are sensitive to the drug, recourse to other accepted measures must be considered.

Carbamazepine is not a simple analgesic and should not be used to relieve trivial facial pains or headaches.

**Pediatrics (< 18 years of age)**
The safety and efficacy of carbamazepine have not been established in patients under 18 years of age and its use in this age group is not recommended.

**Treatment of Acute Mania and Prophylaxis in Bipolar (Manic-Depressive) Disorders:**

**Adults (>18 Years of age)**
TARO-CARBAMAZEPINE may be used as a monotherapy or as an adjunct to lithium in the treatment of acute mania or prophylaxis of bipolar (manic-depressive) disorders in patients who are resistant to or are intolerant of conventional antimanic drugs. Carbamazepine may be a useful alternative to neuroleptics in such patients. Patients with severe mania, dysphoric mania or rapid cycling who are non-responsive to lithium may show a positive response when treated with carbamazepine.

It is important to note that these recommendations are based on extensive clinical experience and some clinical trials versus active comparison agents.

**Pediatrics (< 18 years of age)**
The safety and efficacy of carbamazepine have not been established in patients under 18 years of age and its use in this age group is not recommended.

**Geriatrics (> 65 years of age)**
For all indications, due to drug interactions and different antiepileptic drug pharmacokinetics, the dosage of TARO-CARBAMAZEPINE should be selected with caution in elderly patients. (see Warnings and Precautions, Special Populations, Geriatrics and Dosage and Administration, Dosing Considerations, Geriatrics).

**CONTRAINDICATIONS**

TARO-CARBAMAZEPINE (carbamazepine) is contraindicated in:

- Patients who are hypersensitive to carbamazepine or to any of the components of the tablets or suspension. For a complete listing, see Dosage Forms, Composition and Packaging section of the product monograph.

- Patients who are hypersensitive to any of the tricyclic compounds, such as: amitriptyline, trimipramine, imipramine, or their analogues or metabolites, because of the similarity in chemical structure.
- Patients with hepatic disease, a history of bone-marrow depression, a history of hepatic porphyria (acute intermittent porphyria, variegate porphyria, porphyria cutanea tarda), or serious blood disorder.

- Conjunction with, or immediately after a monoamine oxidase (MAO) inhibitor (see DRUG INTERACTIONS).

- Conjunction with itraconazole and voriconazole (see DRUG INTERACTIONS).

- Patients presenting atrioventricular heart block (see WARNINGS AND PRECAUTIONS, Cardiovascular).

### WARNINGS AND PRECAUTIONS

#### Serious Warnings and Precautions

**HAEMATOLOGIC:** Although reported infrequently, serious adverse effects have been observed during the use of carbamazepine. Agranulocytosis and aplastic anemia with a fatal outcome have occurred very rarely. Leucopenia, thrombocytopenia, hepatocellular and cholestatic jaundice, and hepatitis have also been reported. However, in the majority of cases, leucopenia and thrombocytopenia were transient and did not signal the onset of either aplastic anemia or agranulocytosis. It is important that TARO-CARBAMAZEPINE (carbamazepine) should be used carefully and close clinical and frequent laboratory supervision should be maintained throughout treatment in order to detect as early as possible signs and symptoms of a possible blood dyscrasia. TARO-CARBAMAZEPINE should be discontinued if any evidence of significant bone marrow depression appears (See WARNINGS AND PRECAUTIONS).

**DERMATOLOGIC:** Steven’s-Johnson Syndrome and Toxic Epidermal Necrolysis: Serious and sometimes fatal dermatologic reactions, including Toxic Epidermal Necrolysis (TEN) and Stevens-Johnson Syndrome (SJS), have been reported with carbamazepine. In countries with mainly Caucasian populations, these reactions are estimated to occur in 1 to 6 per 10,000 new users, but in some Asian countries (e.g., Taiwan, Malaysia and the Philippines) the risk is estimated to be about 10 times higher.

Human Leukocyte Antigens (HLA)-A*3101 and HLA-B*1502 may be risk factors for the development of serious cutaneous adverse drug reactions. Retrospective genome-wide studies in Japanese and Northern European populations reported an association between severe skin reactions (SJS, TEN, Drug Rash with Eosinophilia and Systemic Symptoms (DRESS), Acute Generalized Exanthematous Pustulosis (AGEP) and maculopapular rash) associated with carbamazepine use and the presence of the HLA-A*3101 allele in these
patients. Similarly, in studies that included small samples of patients of Han Chinese ancestry a strong association was found between the risk of developing SJS/TEN and the presence of the HLA-B*1502 allele. The HLA-B*1502 allele is found almost exclusively in individuals with ancestry across broad areas of Asia†. It is therefore, recommended that physicians consider HLA-A*3101 and HLA-B*1502 genotyping as a screening tool in genetically at-risk populations (see WARNINGS AND PRECAUTIONS - Ancestry and Allelic Variations in the HLA-A Gene and Ancestry and Allelic Variations in the HLA-B Gene). Until further information is available, the use of TARO-CARBAMAZEPINE and other anti-epileptic drugs associated with SJS/TEN should be avoided in patients who test positive for the HLA-A*3101 or HLA-B*1502 alleles (see WARNINGS AND PRECAUTIONS, Ancestry and Allelic Variations in the HLA-A Gene, Ancestry and Allelic Variation in the HLA-B Gene, Important Limitations of HLA-A and HLA-B Genotyping).

**Treatment recommendations for dermatological reactions:** TARO-CARBAMAZEPINE should be discontinued at the first sign of a rash, unless the rash is clearly not drug-related. If signs or symptoms suggest SJS/TEN, use of this drug should not be resumed and alternative therapy should be considered. The use of other anti-epileptic drugs associated with SJS/TEN should be avoided in patients who have shown severe dermatological reactions during TARO-CARBAMAZEPINE treatment.

**Carcinogenicity:** Long-term toxicity studies in rats indicated a potential carcinogenic risk (see TOXICOLOGY). Therefore, the possible risk of the drug must be weighed against the potential benefits before prescribing TARO-CARBAMAZEPINE to individual patients.

**Pharmacogenomics**

There is growing evidence of the role of different HLA alleles in predisposing patients to immune-mediated adverse reactions.

**Ancestry and Allelic Variation in the HLA-A Gene**

† The following rates provide a rough estimate of the prevalence of HLA-B*1502 in various populations From 2 to 12% in Han Chinese populations, about 8% in Thai populations, and above 15% in the Philippines and some Malaysian populations. Allele frequencies up to about 2% and 6% have been reported in Korea and India, respectively. The frequency of the HLA-B*1502 allele is negligible in persons from European descent, several African populations, indigenous peoples of the Americas, Hispanic populations sampled and in Japanese (< 1%). The estimated frequencies have limitations due to the wide variation in allele frequencies that exist within ethnic groups, the difficulties in ascertaining ethnic ancestry and the likelihood of mixed ancestry.
The frequency of the HLA-A*3101 allele, an inherited allelic variant of the HLA-A gene, varies widely between ethnic populations and its frequency is about 2 to 5% in European populations and about 10% in the Japanese population. The frequency of this allele is estimated to be less than 5% in the majority of Australian, Asian, African and North American populations with some exceptions within 5-12%. Prevalence above 15% has been estimated in some ethnic groups in South America (Argentina and Brazil), North America (US Navajo and Sioux, and Mexico Sonora Seri) and Southern India (Tamil Nadu) and between 10%-15% in other native ethnicities in these same regions.

Testing for the presence of HLA-A*3101 allele should be considered in patients with ancestry in genetically at-risk populations (for example, patients of the Japanese and Caucasian populations, patients who belong to the indigenous populations of the Americas, Hispanic populations, people of southern India, and people of Arabic descent), prior to initiating treatment with TARO-CARBAMAZEPINE (see WARNINGS AND PRECAUTIONS, Important Limitations of HLA-A and HLA-B Genotyping). The use of TARO-CARBAMAZEPINE should be avoided in patients who are found to be positive for HLA-A*3101, unless the benefits clearly outweigh the risks. Screening is generally not recommended for any current TARO-CARBAMAZEPINE users, as the risk of SJS/TEN, AGEP, DRESS and maculopapular rash is largely confined to the first few months of therapy, regardless of HLA-A*3101 status (see WARNINGS AND PRECAUTIONS, Important Limitations of HLA-A and HLA-B Genotyping).

Ancestry and Allelic Variation in the HLA-B Gene

In studies that included small samples of carbamazepine-treated patients of Han Chinese and Thai origin, a strong association was found between the risk of developing SJS/TEN and the presence of HLA-B*1502, an inherited allelic variant of the HLA-B gene. The HLA-B*1502 allele is found almost exclusively in individuals with ancestry across broad areas of Asia. Results of these studies suggest that the presence of the HLA-B *1502 allele may be one of the risk factors for carbamazepine-associated SJS/TEN in patients with Asian ancestry. Therefore, physicians should consider HLA-B*1502 genotyping as a screening tool in these patients. Until further information is available, the use of TARO-CARBAMAZEPINE and other anti-epileptic drugs associated with SJS/TEN should also be avoided in patients who test positive for the HLA-B*1502 allele.

Important Limitations of HLA-A and HLA-B Genotyping

HLA-A*3101 and HLA-B*1502 genotyping as a screening tool have important limitations and must never substitute for appropriate clinical vigilance and patient management. Many patients positive for HLA-A*3101 and treated with TARO-CARBAMAZEPINE
will not develop SJS, TEN, DRESS, AGEP or maculopapular rash and patients negative for HLA-A*3101 of any ethnicity can still develop these severe cutaneous adverse reactions. Similarly, many HLA-B*1502-positive Asian patients treated with TARO-CARBAMAZEPINE will not develop SJS/TEN, and these reactions can still occur infrequently in HLA-B*1502-negative patients of any ethnicity. The role of other possible factors in the development of, and morbidity from, these severe cutaneous adverse reactions, such as antiepileptic drug (AED) dose, compliance, concomitant medications, co-morbidities, and the level of dermatologic monitoring have not been studied.

In addition, it should be kept in mind that over 90% of carbamazepine treated patients who will experience SJS/TEN have this reaction within the first few months of treatment. This information may be taken into consideration when deciding whether to screen genetically at-risk patients currently on TARO-CARBAMAZEPINE.

The identification of subjects carrying the HLA-B*1502 allele and the avoidance of carbamazepine therapy in these subjects has been shown to decrease the incidence of carbamazepine-induced SJS/TEN.

Should signs and symptoms suggest a severe skin reaction such as SJS or TEN, TARO-CARBAMAZEPINE should be withdrawn at once.

**Hypersensitivity**

TARO-CARBAMAZEPINE can trigger hypersensitivity reactions, including DRESS, a delayed multi-organ hypersensitivity disorder with fever, rash, vasculitis, lymphadenopathy, pseudo lymphoma, arthralgia, leukopenia, eosinophilia, hepato-splenomegaly, abnormal liver function tests and vanishing bile duct syndrome (destruction and disappearance of the intrahepatic bile ducts), that may occur in various combinations. One or more organs such as skin, liver, lungs, kidneys, pancreas, myocardium, bone marrow, spleen, thymus, lymph nodes and colon may be affected (see section **ADVERSE REACTIONS**).

The HLA-A*3101 allele has been found to be associated with the occurrence of hypersensitivity syndrome, including maculopapular rash.

In general, if signs and symptoms suggestive of hypersensitivity reactions occur, TARO-CARBAMAZEPINE should be withdrawn immediately, and alternative therapy should be considered.

Patients who have exhibited hypersensitivity reactions to carbamazepine should be informed that approximately 25 to 30% of these patients may experience hypersensitivity reactions with oxcarbazepine (Trileptal®).

Cross-hypersensitivity can occur between carbamazepine and phenytoin.
General

A tolerance may develop to the action of carbamazepine after a few months of treatment and should be watched for (see PART II: SCIENTIFIC INFORMATION-CLINICAL TRIALS).

TARO-CARBAMAZEPINE should not be used in conjunction with the antiretroviral agent delavirdine due to potential for loss of virologic response and possible resistance to delavirdine or to the class of nonnucleoside reverse transcriptase inhibitors.

Anticholinergic effects

Like other tricyclic compounds, carbamazepine has a moderate anticholinergic action which is responsible for some of its side effects. Because of its anticholinergic action, carbamazepine should be given cautiously, if at all, to patients with increased intraocular pressure or urinary retention.

Special excipients

Carbamazepine oral suspension contains parahydroxybenzoates which may cause allergic reactions (possibly delayed).

Carcinogenesis and Mutagenesis

Long-term toxicity studies in rats indicated a potential carcinogenic risk (see TOXICOLOGY). Therefore, the possible risk of the drug must be weighed against the potential benefits before prescribing TARO-CARBAMAZEPINE to individual patients.

Cardiovascular

TARO-CARBAMAZEPINE should be used cautiously in patients with a history of coronary artery disease, organic heart disease, or congestive heart failure. Carbamazepine may suppress ventricular automaticity due to its membrane-depressant effect, similar to that of quinidine and procainamide, associated with suppression of phase 4 depolarization of the heart muscle fiber (see PART II: SCIENTIFIC INFORMATION-CLINICAL TRIALS).

If a defective conductive system is suspected, an ECG should be performed before administering TARO-CARBAMAZEPINE, in order to exclude patients with atrioventricular block.

Bone Disorders

Long-term use of antiepileptics such as carbamazepine, phenobarbital, phenytoin, primidone, oxcarbazepine, lamotrigine and sodium valproate is associated with a risk of decreased bone mineral density that may lead to weakened or brittle bones.
Endocrine and Metabolism

Patients with Fructose Intolerance

TARO-CARBAMAZEPINE chewable tablets and oral suspension contain sorbitol and, therefore, should not be administered to patients with rare hereditary problems of fructose intolerance.

Hyponatremia

Hyponatremia is known to occur with carbamazepine. Although hyponatremia occurs in 10 to 15% of patients taking carbamazepine, it is seldom symptomatic or severe enough to cause fluid retention. In patients with pre-existing renal conditions associated with low sodium or in patients treated concomitantly with sodium-lowering medicinal products (e.g. diuretics, medicinal products associated with inappropriate ADH secretion), serum sodium levels should be measured prior to initiating carbamazepine therapy. Thereafter, serum sodium levels should be measured after approximately two weeks and then at monthly intervals for the first three months during therapy, or according to clinical need. These risk factors may apply especially to the elderly and renally-compromised patients. If hyponatremia is observed, water restriction is an important counter-measurement if clinically indicated.

Hypothyroidism

Carbamazepine can reduce serum concentrations of thyroid hormones through enzyme induction requiring an increase in dose of thyroid replacement therapy in patients with hypothyroidism. In order to adjust the dosage of thyroid replacement therapy, evaluation of thyroid hormone status should be considered for patients treated with TARO-CARBAMAZEPINE, particularly for pediatric patients, due to the potential risk of hypothyroidism and long-term adverse effects on development that can occur in relation to undetected changes in thyroid hormone status.

Neurologic

Increased Seizure Frequency

Abrupt withdrawal of TARO-CARBAMAZEPINE may precipitate seizures. Therefore, if carbamazepine has to be discontinued, it should be withdrawn gradually over a 6-month period. In epileptic patients, the switch to the new antiepileptic compound should be made under cover of a suitable drug.

TARO-CARBAMAZEPINE should be used with caution in patients with mixed seizures which includes absences, either typical or atypical. In all these conditions, carbamazepine may exacerbate seizures. In the event of exacerbation of seizures, TARO-CARBAMAZEPINE should be discontinued.
The occurrence of CNS adverse reactions may be a manifestation of relative overdosage or significant fluctuation in plasma levels. In such cases, it is advisable to monitor the plasma levels.

A number of investigators have reported a deterioration of EEG abnormalities with regard to focal alterations and a higher incidence of records with nil beta-activity; during carbamazepine-combined treatment (see **PART II: SCIENTIFIC INFORMATION-CLINICAL TRIALS**).

**Driving and using Hazardous Machines**

Patients’ ability to react may be impaired by their medical condition resulting in seizures and adverse reactions reported with carbamazepine, including dizziness, drowsiness, ataxia, diplopia, impaired accommodation and blurred vision. Patients should be advised not to drive or use complex machines, or engage in other hazardous activities, until they have gained sufficient experience on carbamazepine to gauge whether it affects their mental and/or motor performance adversely.

**Psychiatric**

Because it is closely related to the other tricyclic drugs, there is some possibility that carbamazepine might activate a latent psychosis, or, in elderly patients, produce agitation or confusion, especially when combined with other drugs. Caution should also be exercised in patients with alcohol dependence.

**Suicidal Ideation and Behaviour**

Suicidal ideation and behaviour have been reported in patients treated with antiepileptic agents in several indications.

All patients treated with anti epileptic drugs, irrespective of indication, should be monitored for signs of suicidal ideation and behaviour and appropriate treatment should be considered. Patients (and caregivers of patients) should be advised to seek medical advice should signs of suicidal ideation or behaviour emerge.

An FDA meta-analysis of randomized placebo controlled trials, in which antiepileptic drugs were used for various indications, has shown a small increased risk of suicidal ideation and behaviour in patients treated with these drugs. The reason for this risk is not known.

There were 43892 patients treated in the placebo controlled clinical trials that were included in the meta-analysis. Approximately 75% of patients in these clinical trials were treated for indications other than epilepsy and, for the majority of non-epilepsy indications the treatment (antiepileptic drug or placebo) was administered as monotherapy. Patients with epilepsy represented approximately 25% of the total number of patients treated in the placebo controlled clinical trials and, for the majority of epilepsy patients, treatment (antiepileptic drug or placebo) was administered as adjunct to other antiepileptic agents (i.e., patients in both treatment arms were being treated with one or more antiepileptic drug). Therefore, the small increased risk of suicidal ideation and behaviour reported from the meta-analysis (0.43% for patients on
antiepileptic drugs compared to 0.24% for patients on placebo) is based largely on patients that received monotherapy treatment (anti epileptic drug or placebo) for non-epilepsy indications. The study design does not allow for an estimation of the risk of suicidal ideation and behaviour for patients with epilepsy that are taking antiepileptic drugs, due both to this population being the minority in the study, and the drug-placebo comparison in this population being confounded by the presence of adjunct antiepileptic drug treatment in both arms.

**Risk of Suicide in Patients with Bipolar Disorder**

Patients with bipolar disorder may experience worsening of their depressive symptoms and/or the emergence of suicidal ideation and behaviours (suicidity) whether or not they are taking medications for bipolar disorder. Patients should be closely monitored for clinical worsening (including development of new symptoms) and suicidality, especially at the beginning of a course of treatment, or at the time of dose changes.

In addition, patients with a history of suicidal behavior or thoughts, those patients exhibiting a significant degree of suicidal ideation prior to commencement of treatment, and young adults, are at an increased risk of suicidal thoughts or suicide attempts, and should receive careful monitoring during treatment.

Patients (and caregivers of patients) should be alerted about the need to monitor for any worsening of their condition (including development of new symptoms) and/or the emergence of suicidal ideation/behavior or thoughts of harming themselves and to seek medical advice immediately if these symptoms present.

Prescriptions for all medications, including TARO-CARBAMAZEPINE (carbamazepine), should be written for the smallest quantity of tablets consistent with good patient management, in order to reduce the risk of overdose.

**Sexual Function/Reproduction**

There have been very rare reports of impaired male fertility and/or abnormal spermatogenesis.

**Skin**

Mild skin reactions, e.g. isolated macular or maculopapular exanthema, usually disappear within a few days or weeks, either during continued course of treatment or following a decrease in dosage. However, the patient should be kept under close surveillance because of the rare possibility of Steven-Johnson syndrome or Toxic Epidermal Necrolysis occurring (see WARNINGS AND PRECAUTIONS, Serious Warnings and Precautions, DERMATOLOGIC).

In addition to being associated with severe adverse cutaneous reactions (see WARNINGS AND PRECAUTIONS), the HLA-A*3101 allele has been found to be associated with less severe adverse cutaneous reactions from carbamazepine, and may predict the risk of such reactions as anticonvulsant hypersensitivity syndrome or non-serious rash (maculopapular eruption). However, the HLAB*1502 allele has not been found to predict the risk of these aforementioned
skin reactions (see WARNINGS AND PRECAUTIONS, Ancestry and Allelic Variation in the HLA-A Gene).

Special Population

Pregnant Women

Pregnancy

Women with epilepsy who are, or intend to become pregnant, should be treated with special care.

In women of childbearing potential, TARO-CARBAMAZEPINE should, whenever possible, be prescribed as monotherapy, because the incidence of congenital abnormalities in the offspring of women treated with more than one antiepileptic drug is greater than in those of women receiving a single antiepileptic. The risk of malformations following exposure to carbamazepine as polytherapy may vary depending on the specific drugs used and may be higher in polytherapy combinations that include valproate.

If pregnancy occurs in a woman receiving TARO-CARBAMAZEPINE or if the problem of initiating TARO-CARBAMAZEPINE arises during pregnancy, the drug's potential benefits must be weighed against its hazards, particularly during the first 3 months of pregnancy. TARO-CARBAMAZEPINE should not be discontinued or withheld from patients if required to prevent major seizures because of the risks posed, to both mother and fetus, by status epilepticus with attendant hypoxia. During pregnancy, an effective antiepileptic treatment should not be interrupted, since the aggravation of the illness is detrimental to both the mother and the fetus.

The possibility that carbamazepine, like all major antiepileptic drugs, increases the risk of malformations has been reported. Developmental disorders and malformations, including spina bifida, and also other congenital anomalies, e.g. craniofacial defects, cardiovascular malformations, hypospadias, and anomalies involving various body systems, have been reported in association with carbamazepine.

Conclusive evidence from controlled studies with carbamazepine monotherapy is lacking. Patients should be counselled regarding the possibility of an increased risk of malformations and given the opportunity of antenatal screening.

Monitoring and prevention

Folic acid deficiency is known to occur in pregnancy. Antiepileptic drugs have been reported to aggravate folic acid deficiency. This deficiency may contribute to the increased incidence of birth defects in the offspring of treated epileptic women. Folic acid supplementation has therefore been recommended before and during pregnancy.
In the neonate

To prevent neonatal bleeding disorders, Vitamin K₁ administration to the mother during the last weeks of pregnancy, as well as to the newborn, has been recommended.

Cholestatic hepatitis in neonates exposed to carbamazepine in the antenatal period has been reported. Infants of mothers treated with TARO-CARBAMAZEPINE should be carefully observed for adverse hepatobiliary effects. A few cases of neonatal seizures and respiratory depression have been associated with maternal carbamazepine and other concomitant anticonvulsant drug use. A few cases of neonatal vomiting, diarrhea, and/or decreased feeding have also been associated with maternal carbamazepine use. These reactions may represent a neonatal withdrawal syndrome.

Women of child-bearing potential and contraceptive measures

Due to enzyme induction, TARO-CARBAMAZEPINE may result in a failure of the therapeutic effect of oral contraceptive drugs containing estrogen and/or progesterone. Women of child bearing potential should be advised to use alternative contraceptive methods while on treatment with TARO-CARBAMAZEPINE.

It should be noted that the reliability of oral contraceptives may be adversely affected by carbamazepine (see DRUG INTERACTIONS).

Nursing Women

Carbamazepine passes into breast milk in concentrations of about 25 - 60% of the plasma level. No reports are available on the long-term effect of breast-feeding but there have been some reports of cholestatic hepatitis in neonates exposed to carbamazepine during breast feeding. The benefits of breast-feeding should be weighed against the possible risks to the infant and a decision should be made whether to discontinue nursing or to discontinue TARO-CARBAMAZEPINE, taking into account the importance of the drug to the mother. Therefore breast-fed infants of mothers treated with carbamazepine should be carefully observed for adverse reactions such as somnolence, allergic skin reactions and adverse hepatobiliary effects.

Geriatrics (> 65 years of age):

Due to drug interactions and different antiepileptic drug pharmacokinetics, the dosage of TARO-CARBAMAZEPINE should be selected with caution in elderly patients. In general, dose selection for an elderly patient usually starts at the low end of the dosing range, reflecting the greater frequency of decreased hepatic, renal, or cardiac function, and of concomitant disease.

Monitoring and Laboratory Tests

TARO-CARBAMAZEPINE (carbamazepine) should be prescribed only after a critical risk-benefit appraisal in patients with a history of cardiac, hepatic or renal damage, adverse
hematological reactions to other drugs, or interrupted courses of therapy with TARO-CARBAMAZEPINE. **Careful clinical and laboratory supervision should be maintained throughout treatment.** Should any signs or symptoms or abnormal laboratory findings be suggestive of blood dyscrasia or liver disorder, TARO-CARBAMAZEPINE should be immediately discontinued until the case is carefully reassessed.

**Bone marrow function**

Complete blood counts, including platelets and possibly reticulocytes and serum iron, should be carried out before treatment is instituted, and periodically thereafter.

If definitely low or decreased white blood cell or platelet counts are observed during treatment, the patient and the complete blood count should be monitored closely. Non-progressing fluctuating asymptomatic leucopenia, which is encountered, does not generally call for the withdrawal of TARO-CARBAMAZEPINE. However, treatment with TARO-CARBAMAZEPINE should be discontinued if the patient develops leucopenia which is progressive or accompanied by clinical manifestations, e.g. fever or sore throat, as this could indicate the onset of significant bone marrow depression.

**Because the onset of potentially serious blood dyscrasias may be rapid, patients should be made aware of early toxic signs and symptoms of a potential hematological problem, as well as symptoms of dermatological or hepatic reactions.** If reactions such as fever, sore throat, rash, ulcers in the mouth, easy bruising, petechial or purpuric hemorrhage appear, the patient should be advised to consult his/her physician immediately.

**Hepatic function**

Baseline and periodic evaluations of hepatic function must be performed, particularly in elderly patients and patients with a history of liver disease. TARO-CARBAMAZEPINE should be withdrawn immediately in cases of aggravated liver dysfunction or active liver disease.

**Renal function**

Pre-treatment and periodic complete urinalysis and BUN determinations should be performed.

**Ophthalmic examinations**

Carbamazepine has been associated with pathological eye changes. Periodic eye examinations, including slit-lamp funduscopy and tonometry are recommended.

**Plasma levels**

Although correlations between dosage and plasma levels of carbamazepine, and between plasma levels and clinical efficacy or tolerability are rather tenuous, monitoring plasma levels may be useful in the following situations: dramatic increase in seizure frequency/verification of patient compliance; during pregnancy; when treating children or adolescents; in suspected
absorption disorders; in suspected toxicity, especially where more than one drug is being used (see DRUG INTERACTIONS).

ADVERSE REACTIONS

Adverse Drug Reaction Overview

The reactions which have been most commonly reported with carbamazepine are CNS disturbances (e.g. drowsiness, headache, unsteadiness on the feet, diplopia, dizziness), gastrointestinal disturbances (nausea, vomiting), and allergic skin reactions. These reactions usually occur only during the initial phase of therapy, if the initial dose is too high, or when treating elderly patients. They have rarely necessitated discontinuing TAROCARBAMAZEPINE therapy, and can be minimized by initiating treatment at a low dosage.

The occurrence of CNS adverse reactions may be a manifestation of relative overdosage or significant fluctuation in plasma levels. In such cases it is advisable to monitor the plasma levels.

The more serious adverse reactions observed are the hematologic, hepatic, cardiovascular and dermatologic reactions, which require discontinuation of therapy.

The following adverse drug reactions from clinical and post-market experience are listed by MedDRA system organ class. The corresponding frequency category for each adverse drug reaction is based on the following convention (CIOMS III): Very common: (≥1/10); common: (≥1/100 to <1/10); uncommon: (≥1/1,000 to <1/100); rare: (≥1/10,000 to <1/1,000); very rare: (<1/10,000).

Blood and lymphatic system disorders

Very common: leucopenia;
Common: eosinophilia, thrombocytopenia;
Rare: leucocytosis, lymphadenopathy,
Very rare: agranulocytosis, aplastic anemia, pancytopenia, pure red cell aplasia, anemia, macrocytic anemia, megaloblastic anemia, reticulocytosis, thrombocytopenic purpura, and hemolytic anemia. In a few instances, deaths have occurred.

Hepatobiliary disorders

Rare: hepatitis of a cholestatic, parenchymal (hepatocellular), or mixed type, vanishing bile duct syndrome, jaundice;
Very rare: hepatic failure, granulomatous liver disease

Skin and subcutaneous tissue disorders

Very common: erythematous rashes, urticaria which may be severe, allergic dermatitis-and rashes;
Uncommon: exfoliative dermatitis;
Rare: systemic lupus erythematosus, pruritis;
Very rare: Steven Johnson syndrome‡, toxic epidermal necrolysis (Lyell's syndrome), photosensitivity reaction, erythema multiform, erythema nodosum, pigmentation disorder, purpura, acne, diaphoresis, alopecia, neurodermatitis, hirsutism.

Nervous system disorders
Very common: ataxia, dizziness, somnolence;
Common: an increase in motor seizures (see INDICATIONS), diplopia, headache;
Uncommon: abnormal involuntary movements (e.g. tremor, asterixis, dystonia, tics), nystagmus;
Rare: dyskinesia, paresis, eye movement disorder, speech disorders (e.g. dysarthria, slurred speech), choreoathetosis, peripheral neuropathy, paraesthesia, muscle weakness;
Very rare: neuroleptic malignant syndrome, aseptic meningitis with myoclonus and peripheral eosinophilia, dysgeusia.

Cardiac disorders
Rare: cardiac conduction disorders (including second and third degree atrioventricular heart block);
Very rare: arrhythmias, Stokes-Adams in patients with atrioventricular block, bradycardia, congestive cardiac failure, aggravated coronary artery disease. Some of these cardiovascular complications have had fatal outcomes. Myocardial infarction and arrhythmia have been associated with other tricyclic compounds.

Vascular disorders
Rare: hypertension or hypotension;
Very Rare: circulatory collapse, thromboembolism (e.g. pulmonary embolism), thrombophlebitis.

Psychiatric disorders
Rare: hallucinations (visual or auditory), depression, talkativeness, agitation, anorexia, restlessness, confusional state;
Very rare: activation of psychosis. Very rare cases of suicide attempt and completed suicide have been reported, however a causal relationship has not been established.

Renal and urinary disorders
Very rare: tubulointerstitial nephritis, renal failure, renal impairment (e.g. albuminuria, glycosuria, hematuria, oliguria sometimes associated with elevated blood pressure, and blood urea nitrogen increased/azotemia), urinary retention, urinary frequency.

Reproductive system
Very rare: sexual dysfunction/erectile dysfunction, spermatogenesis abnormal (with decreased sperm count and/or motility).

Gastrointestinal disorders
Very common: vomiting, nausea;

‡ In some Asian countries also reported as rare. See WARNINGS.
Common: dry mouth and throat; 
Uncommon: diarrhea, constipation; 
Rare: abdominal pain; 
Very rare: pancreatitis, glossitis, stomatitis;

**Eye disorders**  
*Common:* accommodation disorders (e.g. blurred vision);  
*Very rare:* lenticular opacities, conjunctivitis, retinal changes.

**Ear and labyrinth disorders**  
*Very rare:* hearing disorders (e.g. tinnitus, hyperacusis, hypoacusis), change in pitch perception.

**Endocrine disorders**  
*Common:* edema, fluid retention, weight increase, hyponatremia and blood osmolarity decreased due to antidiuretic hormone (ADH)-like effect occurs, leading in rare cases to water intoxication accompanied by lethargy, vomiting, headache, confusional state, neurological disorders;  
*Very rare:* galactorrhoea, gynecomastia.

**Metabolism and nutrition disorders**  
*Rare:* folate deficiency, decreased appetite;  
*Very rare:* acute porphyria (acute intermittent porphyria and variegate porphyria), non-acute porphyria (porphyria cutanea tarda).

**Musculoskeletal, connective tissue and bone disorders**  
*Very rare:* bone metabolism disorders (decrease in plasma calcium and blood 25-hydroxycholecalciferol) leading to osteomalacia/osteoporosis, arthralgia, myalgia, muscle spasms.

**Respiratory, thoracic and mediastinal system**  
*Very rare:* pulmonary hypersensitivity characterized by fever, dyspnea, pneumonitis or pneumonia.

**Immune system disorders**  
*Rare:* delayed multi-organ hypersensitivity disorder with fever, rashes, vasculitis, lymphadenopathy, pseudo lymphoma, arthralgia, leucopenia, eosinophilia, hepatosplenomegaly, abnormal liver function tests and vanishing bile duct syndrome (destruction and disappearance of the intrahepatic bile ducts), occurring in various combinations. Other organs may also be affected (e.g. lungs, kidneys, pancreas, myocardium, colon);  
*Very rare:* anaphylactic reaction, angioedema, hypogammaglobulinemia.

**General disorders and administration site conditions**  
*Very common:* fatigue.

**Investigations**  
*Very common:* increased gamma-glutamyltransferase (due to hepatic enzyme induction), usually not clinically relevant;
Common: increased blood alkaline phosphatase;  
Uncommon: increased transaminases;  
Very rare: increased intraocular pressure, increased blood cholesterol, increased high density lipoprotein, increased blood triglycerides. Abnormal thyroid function test: decreased L-Thyroxin (free thyroxine, thyroxine, tri-iodothyronine) and increased blood thyroid stimulating hormone, increased blood prolactin (usually without clinical manifestations).

Post-Market Adverse Drug Reactions

The following adverse drug reactions have been derived from post-marketing experience with carbamazepine via spontaneous case reports and literature cases. Because these reactions are reported voluntarily from a population of uncertain size, it is not possible to reliably estimate their frequency which is therefore categorized as not known. Adverse drug reactions are listed according to system organ classes in MedDRA. Within each system organ class, ADRs are presented in order of decreasing seriousness.

Blood and lymphatic system disorders: bone marrow failure.

Gastrointestinal disorders: colitis.

Immune system disorders: Drug Rash with Eosinophilia and Systemic Symptoms (DRESS).

Infections and infestations: reactivation of human herpesvirus 6 infection.

Investigations: bone density decreased.

Musculoskeletal, connective tissue and bone disorders: fracture.

Nervous system disorders: sedation, memory impairment.

Skin and subcutaneous tissue disorders: Acute Generalized Exanthematous Pustulosis (AGEP), lichenoid keratosis, onychomadesis.

DRUG INTERACTIONS

Overview

Cytochrome P450 3A4 (CYP3A4) is the main enzyme responsible for metabolizing carbamazepine.

Enzyme Inhibition

Co-administration of CYP3A4 inhibitors may increase carbamazepine plasma concentrations and induce adverse reactions. Drugs that have been shown, or would be expected, to increase plasma carbamazepine levels include:
cimetidine, danazol, diltiazem, macrolides, erythromycin, troleandomycin, clarithromycin, fluoxetine, fluvoxamine, nefazodone, loratadine, terfenadine, isoniazid, niacinamide, nicotinamide, propoxyphene, azoles (e.g., ketaconazole, itraconazole, fluconazole), acetzolamide, verapamil, grapefruit juice, protease inhibitors, valproate.

Human microsomal epoxide hydrolase has been identified as the enzyme responsible for the formation of the 10,11-transdiol derivative from carbamazepine-10,11 epoxide. Co-administration of inhibitors of human microsomal epoxide hydrolase may result in increased carbamazepine-10,11 epoxide plasma concentrations. Drugs that have been shown, or are expected, to inhibit the Human microsomal epoxide hydrolase include: Valproate, Quetiapine, felbamate, loxapine.

**Enzyme Induction**

Co-administration of CYP3A4 inducers may increase the rate of carbamazepine metabolism leading to a potential decrease in carbamazepine serum levels and therapeutic effect. Alternatively, discontinuation of a CYP3A4 inducer may decrease the rate of metabolism of carbamazepine, leading to an increase in carbamazepine plasma levels. Drugs that have been shown, or that would be expected, to decrease plasma carbamazepine levels include:

- cisplatin, doxorubicin HCl, felbamate rifampin, phenobarbital, phenytoin, primidone, methsuximide, theophylline.

Carbamazepine is a potent inducer of CYP3A4 and other phase I and phase II enzyme systems in the liver, and may therefore reduce plasma concentrations of co-medications mainly metabolized by CYP3A4 by induction of their metabolism.

Carbamazepine, like other psycho-active drugs, may reduce the patient's alcohol tolerance; it is therefore advisable to abstain from alcohol consumption during treatment.

**Drug-Drug Interactions**

**Effects of TARO-CARBAMAZEPINE on Plasma Levels of Concomitant Agents**

Carbamazepine may lower the plasma level, or diminish or even abolish the activity of certain drugs. The dosage of the following drugs may have to be adjusted to clinical requirements when administered with TARO-CARBAMAZEPINE:

- Analgesics, anti-inflammatory agents: buprenorphine, methadone, paracetamol (long term administration of carbamazepine and paracetamol (acetaminophen) may be associated with hepatotoxicity), phenazone (antipyrine), tramadol.

- Antibiotics: doxycycline, rifabutin.

\(\chi\) Increased levels of the active 10, 11-epoxide

\(\$\) Decreased levels of carbamazepine and increased levels of the 10, 11-epoxide
Anticoagulants: oral anticoagulants (warfarin, phenprocoumon, dicoumarol and acenocoumarol).

Antidepressants: bupropion, citalopram, mianserin, nefadozone, sertraline, trazodone, tricyclic antidepressants (e.g. imipramine, amitriptyline, nortriptyline, clomipramine).
Antiemetics: aprepitant.

Antiepileptics: oxcarbazepine, clobazam, clonazepam, ethosuximide, primidone, valproic acid, felbamate lamotrigine, zonisamide tiagabine, topiramate. Phenytoin plasma levels have been reported both to be raised and lowered by carbamazepine. Phenytoin has also been shown to decrease carbamazepine plasma levels. To avoid phenytoin intoxication and subtherapeutic concentrations of carbamazepine, it is recommended to monitor the plasma concentration of both drugs during titration and adjust dosage accordingly. Mephenytoin plasma levels have been reported in rare instances to increase.

Antifungals: caspofungin, itraconazole, voriconazole. TARO-CARBAMAZEPINE should not be used in combination with voriconazole or itraconazole (see CONTRAINDICATIONS).

Antihelminitics: praziquantel, albendazole.

Antineoplastics: imatinib, irinotecan, gefitinib, cyclophosphamide, lapatinib, temsirolimus.

Antipsychotics: clozapine, haloperidol and bromperidol, olanzapine, quetiapine, risperidone, zisprasidone, aripiprazole, paliperidone.

Antivirals: protease inhibitors for HIV treatment, (e.g. indinavir, ritonavir, saquinavir), the antiretroviral agent delavirdine.

Anxiolytics: alprazolam, midazolam.

Bronchodilators or anti-asthma drugs: theophylline.

Contraceptives: hormonal contraceptives.

Cardiovascular drugs: calcium channel blockers (dihydropyridine group), e.g. felodipine, digoxin, disopyramide, quinidine, propranolol, simvastatin, atorvastatin, lovastatin, ivabradine.

Corticosteroids: corticosteroids (e.g., prednisolone, dexamethasone).

Drugs used in erectile dysfunction: tadalafil.

Immunosuppressants: cyclosporin, everolimus, tacrolimus, sirolimus.

Thyroid agents: levothyroxine.
Other drug interactions: products containing estrogens and/or progesterones.

Agents that may raise carbamazepine and/or carbamazepine-10,11-epoxide plasma levels

Since an increase in carbamazepine and/or carbamazepine-10,11-epoxide plasma levels may result in adverse reactions (e.g., dizziness, drowsiness, ataxia, diplopia), the dosage of TARO-CARBAMAZEPINE should be adjusted accordingly and the blood levels monitored when used concomitantly with the substances described below.

Analgesics, anti-inflammatory drugs: dextropropoxyphene, ibuprofen.

Androgens: danazol.

Antibiotics: macrolide antibiotics (e.g. erythromycin, troleandomycin, josamycin, clarithromycin, telithromycin), ciprofloxacin.

Antidepressants: possibly desipramine, fluoxetine, fluvoxamine, nefadozone, paroxetine, trazodone, viloxazine.

Antiepileptics: stiripentol, vigabatrin.

Antifungals: azoles (itraconazole, ketoconazole, fluconazole, voriconazole). TARO-CARBAMAZEPINE should not be used in combination with voriconazole or itraconazole (see CONTRAINDICATIONS).

Antihistamines: terfenadine, loratadine.

Antipsychotics: loxapine, olanzapine, quetiapine.

Antituberculosis: isoniazid.

Antivirals: protease inhibitors for HIV treatment (e.g. ritonavir).

Carbonic anhydrase inhibitors: acetazolamide.

Cardiovascular drugs: verapamil, diltiazem.

Gastrointestinal drugs: cimetidine, omeprazole.

Muscle relaxants: oxybutynin, dantrolene.

Platelet aggregation inhibitors: ticlopidine.

Other interactions: nicotinamide
Loxapine, felbamate, quetiapine, primidone, valproic acid and valpromide were reported to increase concentration of the active metabolite carbamazepine-10,11-epoxide.

**Agents that may decrease carbamazepine plasma levels**

The dose of TARO-CARBAMAZEPINE may consequently have to be adjusted when used concomitantly with the substances described below.

**Antiepileptics:** felbamate (might decrease the carbamazepine serum concentration associated with an increase in carbamazepine epoxide levels, and might decrease the serum felbamate levels), methsuximide, oxcarbazepine, phenobarbital, phensuximide, phenytoin (to avoid phenytoin intoxication and subtherapeutic concentrations of carbamazepine, it is recommended to monitor the plasma concentration of both drugs during titration (see also Effects of TARO-CARBAMAZEPINE on Plasma Levels of Concomitant Agents)) and fosphenytoin, primidone, progabide, and possibly by clonazepam, valproic acid or valpromide.

**Antineoplastics:** cisplatin or doxorubicin.

**Antituberculosis:** rifampicin.

**Bronchodilatators or anti-asthma drugs:** theophylline, aminophylline.

**Dermatological drugs:** isotretinoin.

**Combinations that require specific consideration**

Concomitant use of carbamazepine and levetiracetam has been reported to increase carbamazepine-induced toxicity (e.g., nystagmus, nausea, vomiting).

Combined use of TARO-CARBAMAZEPINE with lithium, metoclopramide, or haloperidol, may increase the risk of neurotoxic side effects (even in the presence of "therapeutic plasma levels").

Concomitant use of carbamazepine and isoniazid has been reported to increase isoniazid-induced hepatotoxicity.

TARO-CARBAMAZEPINE , like other anticonvulsants, may adversely affect the reliability of hormonal contraceptives; breakthrough bleeding may occur. Accordingly, patients should be advised to use some alternative, non-hormonal method of contraception while taking TARO-CARBAMAZEPINE. Due to enzyme induction TARO-CARBAMAZEPINE may cause failure of the therapeutic effect of oral contraceptive drugs containing estrogen and/or progesterone (e.g. failure of contraception).

Concomitant medication with TARO-CARBAMAZEPINE and some diuretics (hydrochlorothiazide, furosemide) may lead to symptomatic hyponatremia.
Carbamazepine may antagonize the effects of non-depolarising muscle relaxants (e.g., pancuronium); their dosage may need to be raised and patients should be monitored closely for more rapid recovery from neuromuscular blockade than expected.

Isotretinoin has been reported to alter the bioavailability and/or clearance of carbamazepine and carbamazepine 10,11-epoxide; carbamazepine plasma levels should be monitored.

The use of TARO-CARBAMAZEPINE in combination with MAO inhibitors (MAOIs) is contraindicated. Before administering TARO-CARBAMAZEPINE, MAOIs should be discontinued for a minimum of 2 weeks, or longer, if the clinical situation permits (see CONTRAINDICATIONS).

**Drug-Food Interactions**

*Agents that may raise carbamazepine and/or carbamazepine-10,11-epoxide plasma levels:* grapefruit juice.

**Drug-Herb Interactions**

*Agents that may decrease carbamazepine plasma levels:* herbal preparations containing St John’s wort (Hypericum perforatum).

**Drug-Laboratory Interactions**

*Interference with serological testing*

Carbamazepine may result in false positive perphenazine concentrations in HPLC analysis due to interference.

Carbamazepine and the 10,11-epoxide metabolite may result in false positive tricyclic antidepressant concentration in fluorescence polarized immunoassay method.

**DOSAGE AND ADMINISTRATION**

**Dosing Considerations**

*Geriatrics:* Due to drug interactions and different antiepileptic drug pharmacokinetics, the dosage of TARO-CARBAMAZEPINE (carbamazepine) should be selected with caution in elderly patients. In general, dose selection for an elderly patient usually starts at the low end of the dosing range, reflecting the greater frequency of decreased hepatic, renal, or cardiac function, and of concomitant disease.

*Renal impairment/Hepatic impairment:* No data are available on the pharmacokinetics of carbamazepine in patients with any degree of hepatic or renal impairment.
Recommended Dose and Dosage Adjustment

Use in Epilepsy

TARO-CARBAMAZEPINE (carbamazepine) may be used alone or with other anticonvulsants. A low initial daily dosage of TARO-CARBAMAZEPINE with a gradual increase in dosage is advised. To achieve adequate control of seizures, dosage should be adjusted to the needs of the individual patient. Determination of plasma levels may help in establishing the optimum dosage. In the treatment of epilepsy, the dose of carbamazepine should be adjusted to maintain steady state plasma concentration of about 4 - 10 μg/mL (see ACTIONS AND CLINICAL PHARMACOLOGY). TARO-CARBAMAZEPINE should be taken with meals whenever possible.

TARO-CARBAMAZEPINE tablets, chewable tablets and suspension should be taken in 2 to 4 divided doses daily.

TARO-CARBAMAZEPINE chewable tablets and the suspension are particularly suitable for patients who have difficulty swallowing tablets or who need initial careful adjustment of dosage.

The controlled release characteristics of TARO-CARBAMAZEPINE CR reduce the daily fluctuations of plasma carbamazepine. TARO-CARBAMAZEPINE CR tablets (either whole or, if so prescribed, only half a tablet) should be swallowed unchewed with a little liquid during or after a meal. These controlled release tablets should be prescribed as a twice-daily dosage. If necessary, three divided doses may be prescribed. Some patients have been reported to require a dosage increase when switching from tablets to CR tablets. Dosage adjustments should be individualized based on clinical response and, if necessary, plasma carbamazepine levels.

Adults and Children Over 12 Years of Age

Initially, 100 to 200 mg once or twice a day depending on the severity of the case and previous therapeutic history. The initial dosage is progressively increased, in divided doses, until the best response is obtained. The usual optimal dosage is 800 to 1200 mg daily. In rare instances, some adult patients have received 1600 mg. As soon as disappearance of seizures has been obtained and maintained, dosage should be reduced very gradually until a minimum effective dose is reached.

Children 6-12 Years of Age

Initially, 100 mg in divided doses on the first day. Increase gradually by adding 100 mg per day until the best response is obtained. Dosage should generally not exceed 1000 mg daily. As soon as disappearance of seizures has been obtained and maintained, dosage should be reduced very gradually until a minimum effective dose is reached.
**Combination Therapy**

When added to existing anticonvulsant therapy, the drug should be added gradually while the other anticonvulsants are maintained or gradually decreased, except for phenytoin, which may be increased (See **WARNINGS AND PRECAUTIONS, Special Populations: Pregnant Women and DRUG INTERACTIONS**).

**Use in Trigeminal Neuralgia**

The initial daily dosage should be small; 200 mg taken in 2 doses of 100 mg each is recommended. The total daily dosage can be increased by 200 mg/day until relief of pain is obtained. This is usually achieved at dosage between 200 and 800 mg daily, but occasionally up to 1200 mg/day may be necessary. Maximum recommended dose is 1200 mg/day. As soon as relief of pain has been obtained and maintained, progressive reduction in dosage should be attempted until a minimal effective dosage is reached. Because trigeminal neuralgia is characterized by periods of remission, attempts should be made to reduce or discontinue the use of TARO-CARBAMAZEPINE at intervals of not more than 3 months, depending upon the individual clinical course.

Prophylactic use of the drug in trigeminal neuralgia is not recommended.

**Use in Mania and Bipolar (Manic-Depressive) Disorders**

The initial daily dosage should be low, 200 to 400 mg/day, administered in divided doses, although higher starting doses of 400 to 600 mg/day may be used in acute mania. This dose may be gradually increased until patient symptomatology is controlled or a total daily dose of 1600 mg is achieved. Increments in dosage should be adjusted to ensure optimal patient tolerability. The usual dose range is 400 to 1200 mg/day administered in divided doses. Doses used to achieve optimal acute responses and tolerability should be continued during maintenance treatment. When given in combination with lithium and neuroleptics, the initial dosage should be low, 100 mg to 200 mg daily, and then increased gradually. A dose higher than 800 mg/day is rarely required when given in combination with neuroleptics and lithium, or with other psychotropic drugs such as benzodiazepines. Plasma levels are probably not helpful for guiding therapy in bipolar disorders.

**Administration**

TARO-CARBAMAZEPINE suspension should be well shaken before use since improper re-suspension may lead to administering an incorrect dose. Since a given dose of TARO-CARBAMAZEPINE suspension produces higher peak carbamazepine levels than the same dose in tablet form, it is advisable to start with low doses and to increase slowly to avoid adverse reactions. When switching a patient from TARO-CARBAMAZEPINE Tablets to TARO-CARBAMAZEPINE suspension, the same number of mg per day should be given in smaller, more frequent doses (i.e. BID tablets to TID suspension).
OVERDOSAGE

Lowest known lethal dose: estimated 3.2 g (24 year old woman).

Highest known doses survived: 80 g (34 year old man); 34 g (13 year old girl); 1.4 g (23 month old girl).

Symptoms of Overdosage

The presenting signs and symptoms of overdosage usually involve the central nervous, cardiovascular, and respiratory systems, as well as the adverse drug reactions mentioned under the Adverse Reaction section.

Central Nervous System: CNS depression, disorientation, depressed level of consciousness, tremor, restlessness, somnolence, agitation, hallucination, coma, blurred vision, nystagmus, mydriasis, slurred speech, dysarthria, ataxia, dyskinesia, abnormal reflexes (slowed/hyperactive), convulsions, psychomotor disturbances, myoclonus, opisthotonos, hypothermia/ hyperthermia, flushed skin/cyanosis, EEG changes.

Respiratory System: respiratory depression, pulmonary edema.

Cardiovascular System: tachycardia, hypotension/hypertension, conduction disturbance with widening of QRS complex, syncope in association with cardiac arrest.

Gastrointestinal System: nausea, vomiting, delayed gastric emptying, reduced bowel motility.

Musculoskeletal system: There have been some cases which reported rhabdomyolysis in association with carbamazepine toxicity.

Renal Function: urinary retention, oliguria or anuria; fluid retention, and water intoxication.

Laboratory Findings: hyponatremia, hypokalemia, leukocytosis, reduced white cell count, metabolic acidosis, hyperglycemia, glycosuria, acetonuria, increased muscle creatine phosphokinase.

Treatment of Overdosage

For management of suspected drug overdose, contact immediately your regional Poison Control Center.

There is no known specific antidote to TARO-CARBAMAZEPINE (carbamazepine).

Evacuate the stomach, with an emetic or by gastric lavage, and then administer activated charcoal. Delay in evacuating the stomach may result in delayed absorption, leading to relapse during recovery from intoxication.
Hemodialysis is the effective treatment modality in the management of the carbamazepine overdose.

Vital signs, including electrocardiogram to detect any cardiac arrhythmias or conduction defects, should be watched and symptomatic treatment should be administered as required. Hyperirritability or convulsions should be appropriately managed by standard medical care.

Hyponatremia should be appropriately managed by standard medical care.

Shock (circulatory collapse) should be treated with supportive measures, including intravenous fluids, oxygen, and corticosteroids.

Charcoal hemoperfusion has been recommended.

Relapse and aggravation of the symptomatology on the 2nd or 3rd day after overdose, due to delayed absorption, should be anticipated.

**ACTIONS AND CLINICAL PHARMACOLOGY**

**Pharmacodynamics**

TARO-CARBAMAZEPINE (carbamazepine) has anticonvulsant properties which have been found useful in the treatment of partial seizures (simple or complex) with and without secondary generalization, and generalized tonic clonic seizures. A mild psychotropic effect has been observed in some patients, which seems related to the effect of carbamazepine in localization-related epilepsies and syndromes.

**Pharmacokinetics**

**Absorption:** The absorption of carbamazepine in man is relatively slow. When taken in a single oral dose, carbamazepine tablets and chewable tablets yield peak plasma concentrations of unchanged carbamazepine within 4 - 24 hours. With respect to the quantity of carbamazepine absorbed, there is no clinically relevant difference between the various dosage forms. However, carbamazepine suspension is absorbed somewhat faster than the tablet; peak plasma levels are reached within 2 hours. Following BID dosage regimens, higher peak levels and lower trough levels are obtained with the suspension than with the tablets. Steady-state plasma levels are comparable for carbamazepine suspension given TID and carbamazepine tablets given BID, when administered at the same total daily dose.

Ingestion of food has no significant influence on the rate and extent of absorption regardless of the dosage form of carbamazepine.

When carbamazepine controlled-release tablets are administered repeatedly, they yield a lower average maximal concentration of carbamazepine in the plasma, without a reduction in the
average minimal concentration. This tends to result in a lower incidence of intermittent concentration-dependent adverse drug reactions. It also ensures that the plasma concentrations remain largely stable throughout the day, thereby making it possible to manage with a twice-daily dosage.

In patients with epilepsy, the therapeutic range for the steady-state plasma concentration of carbamazepine generally lies between 4 - 10 μg/mL.

**Distribution:** Carbamazepine becomes bound to serum proteins to the extent of 70 - 80%. The concentration of unchanged substance in the saliva reflects the nonprotein-bound portion present in the serum (20 - 30%).

**Metabolism:** Carbamazepine is catabolized into its primary pharmacologically active metabolite, carbamazepine-10,11 epoxide, which is then further metabolized primarily into carbamazepine 10,11-transdiol. A small portion of the carbamazepine-10,11 epoxide is also converted into 9-hydroxymethyl-10-carbamoyl-acridan. Additional biotransformation products include various monohydroxylated compounds and the N-glucuronide of carbamazepine produced by UGT2B7.

The elimination half-life of unchanged carbamazepine in the plasma averages approximately 36 hours following a single oral dose. Repeated administration leads to autoinduction of hepatic enzymes and an elimination half-life of only 16-24 hours, depending on the length of the treatment. In patients receiving concomitant treatment with other enzyme-inducing antiepileptic agents, half-life values averaging 9 -10 hours have been found. The mean elimination half-life of carbamazepine-10,11 epoxide in the plasma is about 6 hours following single oral doses of the epoxide itself. One study in 39 children (aged 3-10 years) and 79 adults (aged 15-65 years) suggests that carbamazepine elimination may be slightly enhanced in children. This data suggests that children may require higher doses of carbamazepine (in mg/kg) than adults.

**Excretion:** Only 2 - 3% of carbamazepine, whether administered as a single or in repeated doses, is excreted in the urine in an unchanged form. Approximately 30% of carbamazepine is renally eliminated via the carbamazepine-10,11 epoxide pathway with carbamazepine 10,11-trans-diol as the main urinary metabolite.

**Comparative Bioavailability Studies**

**Carbamazepine Tablets - Immediate Release**

One bioavailability study was performed in order to establish bioequivalence between Taro-Carbamazepine immediate release tablets and the brand product.

A randomized, single dose, two-period, crossover, pivotal comparative bioequivalence study of test carbamazepine immediate release tablets 200 mg (Taro Pharmaceuticals Inc.) with reference carbamazepine immediate release tablets 200 mg (Tegretol® 200 mg, Novartis Pharmaceuticals, Canada) was conducted in 23 healthy male subjects under fasting conditions.
The results are summarized in the table below:

**Oral Suspension**

Two bioavailability studies were performed in order to establish bioequivalence between Taro-Carbamazepine Oral Suspension and the brand product.

A randomized, 2-way crossover, bioequivalence study of carbamazepine suspension administered as a single dose in healthy, adult male volunteers, 18-45 years of age under fasting conditions was conducted (n=23) to compare the rate and extent of absorption of Taro-Carbamazepine Oral Suspension 100 mg/5 mL with the Canadian Reference product, Tegretol Oral Suspension, 100 mg/5 mL, manufactured by Novartis Canada.

The results are summarized in the table below:

**Special Populations and Conditions**

**Geriatrics:** Due to drug interactions and different antiepileptic drug pharmacokinetics, the dosage of TARO-CARBAMAZEPINE should be selected with caution in elderly patients.

**Hepatic Impairment:** No data are available on the pharmacokinetics of carbamazepine in patients with any degree of hepatic impairment.

**Renal Impairment:** No data are available on the pharmacokinetics of carbamazepine in patients with any degree of renal impairment.

**STORAGE AND STABILITY**

TARO- CARBAMAZEPINE Tablets: 25°C (15°C- 30°C) Protect from moisture and light, store in the original container.

TARO- CARBAMAZEPINE CHEWTABS: Store at room temperature (15°C - 30°C). Protect from light and humidity

TARO- CARBAMAZEPINE CR: Store at room temperature (15°C - 25°C) Protect from humidity

TARO- CARBAMAZEPINE Suspension: Store in tightly closed container at room temperature (15°C - 30°C), protect from humidity and light. Discard 2 months after opening.

TARO-CARBAMAZEPINE (carbamazepine) must be kept out of the reach and sight of children.
DOSAGE FORMS, COMPOSITION AND PACKAGING

Availability of Dosage Forms

TARO-CARBAMAZEPINE Tablets 200 mg are white to off-white, round. One side bears the imprint “TC 200” on one side, plain with score on the other. Tablet free of foreign spots or other defects. Available in bottles of 100’s and 500’s.

TARO-CARBAMAZEPINE CHEWTABS 100 mg are white with pink speckles, cherry odour, round, flat. Scored on one side, engraved “TARO” above the score and “16” under the score. Available in Bottles of 100's and 500's, blister packs of 50's and 100's

TARO-CARBAMAZEPINE CHEWTABS 200 mg are white with pink speckles, cherry odour, Oval, flat. Both sides scored, one side “T” engraved above the score line and “27” under the score line. Available in Bottles of 100's and 400's

TARO-CARBAMAZEPINE CR Tablets 200 mg are white to off-white, Capsule shaped. "T12" engraved on one side, scored on both sides. Available in Bottles of 100’s and 500's

TARO-CARBAMAZEPINE CR Tablets 400 mg are white to off-white, Capsule shaped. "T17" engraved on one side, scored on both sides. Available in Bottles of 100’s and 500's

TARO-CARBAMAZEPINE Suspension 100 mg/5 mL is orange in colour. Available in bottles of 450 mL.

Composition

TARO-CARBAMAZEPINE 200 mg tablets contain the following non-medicinal ingredients: Microcrystalline Cellulose, Carboxymethylcellulose Sodium, Colloidal Silicon Dioxide, Magnesium Stearate

TARO-CARBAMAZEPINE CHEWTABS 100 mg and 200 mg contain the following non-medicinal ingredients: Eudragit RS 30D, Diethyl Phthalate, FD & C Red No.40 Lake, Microcrystalline Cellulose, Pregelatinized Starch, Croscarmellose Sodium, Natural Cherry Flavour, Sorbitol, Magnesium Stearat

TARO-CARBAMAZEPINE CR tablets 200 mg and 400 mg contain the following non-medicinal ingredients: Eudragit RS30D, Diethyl Phthalate, Microcrystalline Cellulose, Lactose Monohydrate, Maize Starch, Sodium Starch Glycolate, Magnesium Stearate

TARO-CARBAMAZEPINE Suspensions 100 mg/5 mL contain the following non-medicinal ingredients: Citric acid, FD&C Yellow # 6, orange flavour, poloxamer 188, potassium sorbate, propylene glycol, purified water, sucrose, sorbitol solution, xanthan gum.
PART II: SCIENTIFIC INFORMATION

PHARMACEUTICAL INFORMATION

Drug Substance

Common Name: Carbamazepine
Chemical Name: 5-carbamoyl-5H-dibenzo(b,f)azepine-5carboxamide
Molecular formula and Molecular mass: C_{15}H_{12}N_{2}O and 236.27 g/mol

Structural Formula:

![Structural Formula](image)

Physiochemical properties: Carbamazepine is a white to off-white powder, freely soluble in methylene chloride, sparingly soluble in acetone and in alcohol, practically insoluble in water and in ether.

Specific Rotation: Optically inactive
Melting Point: 189°C to 193°C
Solubility: Practically insoluble in water and in acetone

CLINICAL TRIALS

Evidence supporting the efficacy of carbamazepine as an anticonvulsant was derived from active drug-controlled studies that enrolled patients with the following seizure types:
1. Partial seizures with simple or complex symptomatology.
2. Generalized tonic-clonic seizures.
3. Mixed seizure patterns, which include the above, or other partial or generalized seizures.

Carbamazepine relieves or diminishes the pain associated with trigeminal neuralgia often within 24 to 48 hours.
Carbamazepine given as a monotherapy or in combination with lithium or neuroleptics has been found useful in the treatment of acute mania and the prophylactic treatment of bipolar (manic-depressive) disorders.

A tolerance may develop to the action of carbamazepine after a few months of treatment and should be watched for.

Carbamazepine may suppress ventricular automaticity due to its membrane-depressant effect, similar to that of quinidine and procainamide, associated with suppression of phase 4 depolarization of the heart muscle fiber.

A number of investigators have reported a deterioration of EEG abnormalities with regard to focal alterations and a higher incidence of records with nil β-activity, during carbamazepine-combined treatment.

**DETAILED PHARMACOLOGY**

When administered to mice by the oral route at the dose level of 100 mg/kg, carbamazepine protected all animals against electroshock-induced convulsions (50 mA for 0.2 seconds) for up to 5 hours. In rats, at 50 mg/kg orally, the convulsive threshold was increased by 88 %, and at the dosage of 100 mg/kg, carbamazepine increased the convulsive threshold by about 130%. On the other hand, very minimal effects were noted when carbamazepine was given to mice challenged with picrotoxin and it did not block pentylenetetrazol-induced convulsions.

Carbamazepine has slight sedative and tranquillizing effects in mice but no hypnotic effect except at almost toxic doses. Although intact and spinal animals are influenced in the same way as by muscle relaxants, carbamazepine has no clinically significant muscle relaxant action. In animals, carbamazepine has only a slight anticholinergic effect and no antiemetic activity. Carbamazepine did not inhibit monoamine oxidase in the guinea pig liver at the drug concentration of $1 \times 10^{-3}$M.

In rabbits, carbamazepine administered intravenously could not be given in a dosage sufficient to produce a Stage IV anesthesia (Magnus and Girndt) without toxic effects. Hence, the anesthetic potential is considered nil.

In experimental animals, carbamazepine depresses certain pain reflexes that are mediated by cranial nerves, such as the linguomandibular and infraorbital reflexes. There is no general analgesic effect and non-specific cutaneous pain is not modified by carbamazepine, except at very high doses. In humans, the effect of carbamazepine upon trigeminal or glossopharyngeal pain is probably largely due to blocking of bulbar, thalamic, and higher synapses.

In experimental animals, carbamazepine is rapidly absorbed and rapidly equilibrated between the blood and tissues. It does not accumulate in tissues other than adipose tissue. In the rabbit, carbamazepine is rapidly metabolized and excreted so that blood and tissue levels are very low within 24 hours. Only about 2% is excreted unchanged in the urine.
TOXICOLOGY

Acute Toxicity

In mice, the oral LD$_{50}$ of carbamazepine is between 1100 and 3750 mg/kg; in rats, 3850 - 4025 mg/kg; in rabbits, 1500 - 2680 mg/kg; in guinea pigs, about 920 mg/kg; and in dogs, more than 5620 mg/kg.

The principal toxic effects in these species were laboured breathing, ataxia, clonic and tonic convulsions, and coma. In dogs, toxic doses of carbamazepine induced severe vomiting and defecation, in addition to disturbance of locomotor function.

Subacute and Chronic Toxicity

Subacute and chronic toxicity studies have been carried out on carbamazepine for up to one year at dosage levels of 50, 100, 200 and 400 mg/kg in rats and 50, 100, 150 and 200 mg/kg in the dog. In rats, at 100 and 200 mg/kg/day and above, there was evidence of hepatotoxicity including a slight increase in ALT and histological changes in the liver. At a dosage of 400 mg/kg/day, 25 of 50 animals died, beginning at the 15th week. ALT and BUN levels were slightly increased. The relative organ/body weight ratios were increased for the heart, liver and kidneys.

Carcinogenesis and Genotoxicity

Carbamazepine, when administered to Sprague-Dawley rats for 2 years in the diet at doses of 25, 75 and 250 mg/kg/day, resulted in a dose-related increase in the incidence of hepatocellular tumors in females and in benign interstitial cell adenomas in the testes of males. Carbamazepine must, therefore, be considered to be carcinogenic in Sprague-Dawley rats. Carbamazepine was not found to be genotoxic in various standard bacterial and mammalian mutagenicity studies. The carcinogenicity findings in rats are considered to be not relevant to the use of carbamazepine in humans.

Testicular atrophy and deficient spermatogenesis were observed in a four week oral study with carbamazepine in the rat at 100 mg/kg/day, but were not observed in animals dosed with 200, 500 and 1000 mg/kg/day. In a 24 week study in rats, evidence of testicular atrophy was observed in 3 of 10 animals at 50 mg/kg/day and in one of 10 at 100 mg/kg/day, but no testicular damage was observed at 200 mg/kg/day. In a one year study, inhibition of spermatogenesis and testicular atrophy were noted in 6 of 19 surviving male rats receiving 400 mg/kg/day.

In dogs, there were some macroscopic grey or brownish discolorations of urinary bladders at 100 and 200 mg/kg/day in a 3 month study and at all dose levels (50, 100 and 150 mg/kg/day) in a one year study. Histologically, the brownish pigment was found in the macrophages in the submucosa. The pigment is considered to be a non-toxic metabolite rather than melanin or argentaffin. In one dog, there was minimal hepatic damage after 12 months.
Reproductive Studies

In the course of reproductive studies with carbamazepine in rats and rabbits, approximately 1% of the offspring were listed as having some anomaly.

In the reproductive study in rats, two of the offspring showed kinked ribs bilaterally at doses of 250 mg/kg and 4 animals had cleft palates and talipes at 650 mg/kg. Two of the latter also had anophthalmos. In mice and rats, carbamazepine, when given parenterally, produced a low but nevertheless definite incidence of anomalies including anencephalia, anophthalmos, cleft palates and rudimentary or absent tails. In one study using mice, carbamazepine (40 - 240 mg/kg body weight daily, orally) caused defects (mainly dilatation of cerebral ventricles) in 4.7% of exposed fetuses as compared with 1.3% in controls.

In nursing rats, toxicity was demonstrated by lack of weight gains and unthrifty appearance at the dose level of 200 mg/kg.

PART III: CONSUMER INFORMATION

TARO-CARBAMAZEPINE
(Carbamazepine Tablets)
(Carbamazepine CR Tablets)
(Carbamazepine Chewable Tablets)
(Carbamazepine Oral Suspension)

This leaflet is part III of a three-part "Product Monograph" published when TARO-CARBAMAZEPINE* was approved for sale in Canada and is designed specifically for Consumers. This leaflet is a summary and will not tell you everything about TARO-CARBAMAZEPINE. Contact your doctor or pharmacist if you have any questions about the drug.

ABOUT THIS MEDICATION

What the medication is used for:
Your doctor has prescribed TARO-CARBAMAZEPINE for you:
• to reduce your number of seizures;
• to relieve the pain of trigeminal neuralgia;
• to treat your acute mania or bipolar disorder.

What it does:
TARO-CARBAMAZEPINE belongs to the family of medicines called anticonvulsants for treating epilepsy. TARO-CARBAMAZEPINE is also used for treating the pain of trigeminal neuralgia and for treating mania.

If you have any questions about how TARO-CARBAMAZEPINE works or why this medicine has been prescribed to you, ask your doctor.

When it should not be used:
You should not use TARO-CARBAMAZEPINE if:
• You are allergic (hypersensitive) to carbamazepine or to any of the components of TARO-CARBAMAZEPINE (see What the non-medical ingredients are). If you think you may be allergic, ask your doctor for advice. Do not take TARO-CARBAMAZEPINE if you are allergic to other tricyclic drugs such as amitriptyline, trimipramine, imipramine.
• You have severe heart disease (heart block).
• You have liver disease
• You have a history of bone marrow depression
• You have had serious blood illnesses in the past
• You have a disturbance in the production of porphyrin, a pigment important for liver function and blood formation (also called hepatic porphyria);
• You are also taking drugs belonging to a special group of antidepressants called monoamineoxidase inhibitors (MAOIs).
• You are also taking the drug itraconazole or voriconazole (Vfend) for treatment of an infection.
• TARO-CARBAMAZEPINE should not be used to relieve trivial pain in the face or headaches.
• TARO-CARBAMAZEPINE Chewable tablets and Suspension contain sorbitol which may cause stomach upset and diarrhea. Patients with rare hereditary problems of fructose intolerance should not take this medicine.

If any of the above applies to you, tell your doctor before taking TARO-CARBAMAZEPINE.

What the medicinal ingredient is:
Carbamazepine.

What the non-medical ingredients are:
TARO-CARBAMAZEPINE Tablets 200 mg:
Microcrystalline Cellulose, Carboxymethylcellulose Sodium, Colloidal Silicon Dioxide, Magnesium Stearate.

TARO-CARBAMAZEPINE Chewable Tablets 100 mg and 200 mg: Eudragit RS 30D, Diethyl Phthalate, FD & C Red No.40 Lake, Microcrystalline Cellulose, Pregelatinized Starch, Croscarmellose Sodium, Natural Cherry Flavour, Sorbitol, Magnesium Stearate.

TARO-CARBAMAZEPINE CR 200 mg and 400 mg Tablets: Eudragit RS30D, Diethyl Phthalate, Microcrystalline Cellulose, Lactose Monohydrate, Maize Starch, Sodium Starch Glycolate, Magnesium Stearate.

TARO-CARBAMAZEPINE Suspension 100 mg/5 mL:
Citric Acid, FD&C Yellow # 6, Orange Flavour, Poloxamer 188, Potassium Sorbate, Propylene Glycol, Purified Water, Sucrose, Sorbitol Solution, Xanthan Gum.

What dosage forms it comes in:
TARO-CARBAMAZEPINE is available in the following forms:
• Tablets containing 200 mg carbamazepine.
• CR tablets (controlled-release) containing 200 mg or 400 mg carbamazepine.
• Chewable tablets containing 100 mg or 200 mg carbamazepine.
• Oral suspension: 5 mL (1 measure) containing 100 mg carbamazepine.

<th>WARNING AND PRECAUTIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Serious Warnings and Precautions</strong></td>
</tr>
<tr>
<td><strong>Blood:</strong> Although infrequently reported and very rarely fatal, serious adverse effects affecting the blood cell counts have been observed during the use of carbamazepine. Other side effects include: low white blood cell count, bone marrow depression, hepatitis and signs of liver failure such as jaundice (yellowing of the skin or eyes). Contact your doctor immediately if you are experiencing any of these symptoms. Close clinical and frequent laboratory supervision with your doctor should be maintained throughout treatment with TARO-CARBAMAZEPINE in order to detect as early as possible any possible signs of a blood disorder. Your doctor should discontinue TARO-CARBAMAZEPINE, if there is significant evidence of a bone marrow depression.</td>
</tr>
<tr>
<td><strong>Skin:</strong> Serious skin and sometimes fatal skin reactions known as Toxic Epidermal Necrolysis (TEN) and Stevens-Johnson Syndrome (SJS), have been reported with carbamazepine. Other serious skin reactions such as Drug Rash with Eosinophilia and Systemic Symptoms (DRESS), Acute Generalized Exantheme Pustulosis (AGEP) and Maculopapular Rash have also been reported. Although very rare, serious forms of DRESS and AGEP may also lead to death. Some cases of these skin reactions have been genetically linked. Your doctor may recommend a blood test to determine whether you belong to an at-risk population.</td>
</tr>
<tr>
<td><strong>Contact your doctor immediately if you are developing any combination of:</strong></td>
</tr>
<tr>
<td>- a rash or any serious skin reactions such as red skin, blistering of the lips, eyes or mouth, and skin peeling accompanied by fever</td>
</tr>
<tr>
<td>- swollen lymph nodes</td>
</tr>
<tr>
<td>- joint pain</td>
</tr>
<tr>
<td>- enlargement of the liver and/or the spleen</td>
</tr>
<tr>
<td>- problems related to the lungs, kidneys, pancreas, heart, bone marrow, thymus, and colon</td>
</tr>
</tbody>
</table>

Your doctor will determine if it is indeed drug-related, and discontinue TARO-CARBAMAZEPINE in this case. |
| **Cancer:** Long-term toxicity studies in rats have indicated a possible cancer risk associated with carbamazepine. Before taking TARO-CARBAMAZEPINE, discuss with your doctor the potential benefits and possible risks of this treatment for you. |

---

**BEFORE you use TARO-CARBAMAZEPINE be sure to tell your doctor or pharmacist:** |
| **About your medical conditions, especially if you have or have had any liver, kidney or heart disease or blood disorders (including those caused by other drugs).** |
| **If you have a history, or any family history, of bone disease or have taken antiepileptics (such as phenobarbital, phenytoin, primidone, oxcarbazepine, lamotrigine, sodium valproate and/or carbamazepine) for a prolonged period of time.** |
| **If you are taking delavirdine, a medicine used to treat HIV-1 infection.** |
| **About any allergies you may have, especially if you have ever shown any unusual sensitivity (rash or other signs of allergy) to oxcarbazepine or other drugs used to treat your condition. It is important to note that if you are allergic to TARO-CARBAMAZEPINE there is an approximately 1 in 4 (25%) chance that you could also have an allergic reaction to oxcarbazepine (TRILEPTAL®).** |
| **If you are pregnant. Your doctor may recommend that you take folic acid before and during your pregnancy and vitamin K during the last weeks of pregnancy. Your doctor may also recommend that the newborn receive vitamin K and be observed for liver and gall bladder problems.** |
| **If you are planning on becoming pregnant, discuss the potential benefits against any potential hazards of TARO-CARBAMAZEPINE** |
| **If you are a women taking hormonal contraceptive (birth control medicine), TARO-CARBAMAZEPINE may render this contraceptive ineffective. Therefore, you should use a different or additional non-hormonal method of contraception while you are taking TARO-CARBAMAZEPINE. This should help to prevent an unwanted pregnancy.** |
| **About any other medicines (prescription and nonprescription) you are taking.** |
| **About your usual alcohol consumption.** |
| **If you have increased pressure in the eye (glaucoma).** |
| **If you have difficulty passing urine (urinary retention).** |
If you were told by your physician that you suffer from mental problems, a mental disorder called psychosis that may be accompanied by confusion or agitation, or have thoughts about suicide.

If any of these apply to you, tell your doctor.

- If an allergic reaction happens such as fever with lymph nodes swelling, rash or skin blistering, tell your doctor immediately or go to the emergency department at your nearest hospital. (see Side effects and what to do about them)

- If you experience an increase in the number of seizures, tell your doctor immediately.

- If you experience any side effects such as drowsiness, headache, unsteadiness on the feet, double vision, dizziness, nausea or vomiting, consult your doctor.

- If, at any time, you have thoughts of harming or killing yourself. A small number of people being treated with antiepileptic drugs have reported having such thoughts or behavior. Should this happen to you, or to those in your care if you are a caregiver or guardian, talk to your doctor immediately. Close observation by a doctor is necessary in this situation. Do not discontinue your medication on your own.

- If you have kidney problems associated with low sodium blood level or if you have kidney problems and you are also taking certain medicines that lower sodium blood level (diuretics such as hydrochlorothiazide, furosemide).

TARO-CARBAMAZEPINE may affect male fertility or cause abnormal sperm.

Periodic eye examinations are recommended while taking TARO-CARBAMAZEPINE.

Do not drive a car or operate dangerous machinery until you are sure that TARO-CARBAMAZEPINE does not cause dizziness, drowsiness, sleepiness, blurred or double vision, affect your muscular coordination or affect your alertness.

INTERACTIONS WITH YOUR MEDICATION

Tell your doctor or pharmacist if you are taking or have recently taken any prescription, non-prescription medicines or natural health products. It is particularly important for TARO-CARBAMAZEPINE, since many other medicines interact with it.

You may need a change in your dose or, sometimes, to stop one of these other medicines.

Irregularity of the menstrual period may occur in women taking hormonal contraceptives (birth control medicines) and TARO-CARBAMAZEPINE. The hormonal contraceptive may become less effective and you should consider using other contraceptive methods (non-hormonal).

- Avoid alcohol consumption when taking TARO-CARBAMAZEPINE.

- Do not drink grapefruit juice or eat grapefruit since this can increase the effect of TARO-CARBAMAZEPINE. Other juices, like orange juice or apple juice, do not have this effect.

PROPER USE OF THIS MEDICATION

Usual dose:
Dosage should be individualised. It is very important that you take TARO-CARBAMAZEPINE exactly as your doctor instructed.

- Never increase or decrease the recommended dose of TARO-CARBAMAZEPINE you are taking unless your doctor tells you to.

- If you are taking TARO-CARBAMAZEPINE do not suddenly stop taking it without first checking with your doctor. Your doctor will tell you if and when you can stop taking this medicine.

- TARO-CARBAMAZEPINE Chewable Tablets and Suspension should be taken in 2-4 divided doses daily, with meals whenever possible.

- TARO-CARBAMAZEPINE CR tablets should be swallowed unchewed with a little liquid during or after a meal.

- Shake TARO-CARBAMAZEPINE suspension well before you take it or else you may not receive the correct dose.

Adults and Children Over 12 Years of Age
Initial dose 100 to 200 mg once or twice a day. Your doctor will decide the best dosage for you. Always follow your doctor’s instructions.

For the treatment of trigeminal neuralgia, the maximum dose is 1200 mg a day.

Children 6-12 Years of Age
Initial dose 100 mg in divided doses on the first day. Your doctor will decide the best dosage for you. Always follow your doctor’s instructions.

Overdose:

In case of drug overdose, contact a health care practitioner, hospital emergency department or regional Poison Control Centre immediately, even if there are no symptoms.
Missed Dose:

If you miss a dose, take your TARO-CARBAMAZEPINE as soon as possible. However, if the time is close to the next dose, do not take the missed dose and return to your regular dosing schedule. Do not double the dose to make up for the forgotten dose.

SIDE EFFECTS AND WHAT TO DO ABOUT THEM

Side effects may include:

- purple or reddish-purple bumps that may be itchy
- trembling, uncontrolled body movements, muscle spasm, loss of muscle coordination, weakness
- agitation or hostility (especially in the elderly), depression with restlessness, nervousness or other mood or mental changes, changes in behaviour, confusion, headache, memory loss
- blurred vision, double vision, itching with redness and swelling of the eye (conjunctivitis), uncontrolled eye movements
- difficulty speaking or slurred speech, taste disturbances, dry mouth, red and sore tongue, mouth sores
- ringing or other unexplained sounds in the ears, decreased hearing
- numbness, tingling in hands and feet
- unusual secretion of breast milk, breast enlargement in men, sexual disturbances (erectile dysfunction), male infertility
- increased sensitivity of the skin to sun, alterations in skin pigmentation, acne, increased sweating
- reactivation of herpes virus infection (can be serious when the immune system is depressed)
- complete loss of the nails, loss of hair, excessive body and facial hair
- vomiting, nausea, loss of appetite, constipation, diarrhea, abdominal pain
- dizziness, sleepiness, unsteadiness, drowsiness, fatigue
- weight gain
- aching joints or muscles

Long-term use of antiepileptics such as carbamazepine, phenobarbital, phenytoin, primidone, oxcarbazepine, lamotrigine and sodium valproate is associated with a risk of decreased bone mineral density that may lead to weakened or brittle bones, or fracture

If any of these affects you severely, contact your doctor.

TARO-CARBAMAZEPINE can cause abnormal blood test results. Your doctor will decide when to perform blood tests and will interpret the results.

This is not a complete list of side effects. For any unexpected effects while taking TARO-CARBAMAZEPINE contact your doctor or pharmacist.

**HOW TO STORE IT**

- Taro-Carbamazepine Tablets: 25°C (15°C - 30°C) Protect from moisture and light.
- Taro-Carbamazepine CR Tablets: Store at 15°C - 25°C, protect from humidity.
- Taro-Carbamazepine Chewable Tablets: Store at room temperature (15°C -30°C). Protect from humidity and light.
- Taro-Carbamazepine Suspension: Store in tightly closed container at room temperature (15°C -30°C). Protect from humidity and light. Discard 2 months after opening.
- Keep all medication out of reach and sight of children.

**REPORTING SUSPECTED SIDE EFFECTS**

You can report any suspected adverse reactions associated with the use of health products to the Canada Vigilance Program by one of the following 3 ways:

- Report online at www.healthcanada.gc.ca/medeffect
- Call toll-free at 1-866-234-2345
- Complete a Canada Vigilance Reporting Form and:
  - Fax toll-free to 1-866-678-6789, or
  - Mail to:
    Canada Vigilance Program
    Health Canada
    Postal Locator 0701D
    Ottawa, ON K1A 0K9

Postage paid labels, Canada Vigilance Reporting Form and the adverse reaction reporting guidelines are available on the MedEffectTM Canada Web site at www.healthcanada.gc.ca/medeffect.

*NOTE: Should you require information related to the management of side effects, contact your health professional. The Canada Vigilance Program does not provide medical advice.*

**MORE INFORMATION**

Please consult your doctor or pharmacist with any questions or concerns you may have regarding your individual condition.
