PART II: SCIENTIFIC INFORMATION .................................................................................... 31
Erelzi (etanercept) is a biosimilar biologic drug (biosimilar) to Enbrel®.

PART I: HEALTH PROFESSIONAL INFORMATION

1 INDICATIONS

Indications have been granted on the basis of similarity between Erelzi and the reference biologic drug, Enbrel®.

Erelzi (etanercept) is indicated for:

- treatment of moderately to severely active rheumatoid arthritis (RA) in adults. Treatment is effective in reducing the signs and symptoms of RA, inducing major clinical response, inhibiting the progression of structural damage, and improving physical function. Erelzi can be initiated in combination with methotrexate (MTX) in adult patients or used alone.

- reducing signs and symptoms of moderately to severely active polyarticular juvenile idiopathic arthritis (JIA) in patients aged 4 to 17 years who have had an inadequate response to one or more disease-modifying antirheumatic drugs (DMARDs). Erelzi has not been studied in children less than 4 years of age.

- reducing signs and symptoms of active ankylosing spondylitis (AS).

Improvement may be seen as early as 1 week after initial administration of etanercept in adults, and within 2 weeks in children. Attainment of full effect was usually seen by 3 months in both populations and remained durable thereafter with continued treatment with etanercept. Some patients see continuing improvement after 3 months of treatment with etanercept.

After discontinuation of etanercept, symptoms of arthritis generally returned within a month. Reintroduction of treatment with etanercept in adults after discontinuation of up to 18 months resulted in the same magnitudes of response as patients who received etanercept without interruption of therapy based on results of open-label studies. Reintroduction of etanercept to children after discontinuation up to 4 months also resulted in a subsequent response to therapy.

1.1 Pediatrics

Pediatrics (< 4 years of age):

Erelzi is indicated for treatment of polyarticular juvenile idiopathic arthritis in patients who have had an inadequate response to one or more DMARDs. Erelzi has not been studied in children < 4 years of age.

Only pediatric patients weighing 63 kg (138 pounds) or more, who do not require weight-based dosing, can be treated with the Erelzi 50 mg prefilled syringe or the Erelzi 50 mg SensoReady® Pen. Patients weighing less than 63 kg should be accurately dosed on a mg/kg basis with other etanercept products. (See 4 Dosage and Administration).
1.2 Geriatrics

Geriatrics (> 65 years of age):
Four hundred and eighty RA patients in clinical studies were age 65 or older. No overall differences in safety or effectiveness were observed between these patients and younger patients.

2 CONTRAINDICATIONS

Erelzi is contraindicated in patients who are hypersensitive to this drug or to any ingredient in the formulation, including any non-medicinal ingredient, or component of the container. For a complete listing, see Dosage Forms, Strengths, Composition and Packaging.

- Patients with, or at risk of, sepsis syndrome, such as immunocompromised and HIV+ patients.

3 SERIOUS WARNINGS AND PRECAUTIONS BOX

<thead>
<tr>
<th>Serious Warnings and Precautions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Infections</strong></td>
</tr>
<tr>
<td>- Serious infections leading to hospitalization or death, including sepsis, tuberculosis (TB), invasive fungal and other opportunistic infections, have been observed with the use of TNF blocking agents including etanercept. Cases of TB may be due to reactivation of latent TB infection or to new infection.</td>
</tr>
<tr>
<td>- Treatment with Erelzi should not be initiated in patients with active infections including TB, chronic or localized infections. Administration of Erelzi should be discontinued if a patient develops a serious infection or sepsis.</td>
</tr>
<tr>
<td>- Physicians also should exercise caution when considering the use of Erelzi in patients with a history of recurring or latent infections, including TB, or with underlying conditions, which may predispose patients to infections, such as advanced or poorly controlled diabetes.</td>
</tr>
<tr>
<td>- Before starting treatment with Erelzi, all patients should be evaluated for both active and inactive ('latent') TB. If inactive ('latent') TB is diagnosed, treatment for latent TB should be started with anti-TB therapy before the initiation of Erelzi.</td>
</tr>
<tr>
<td>- Patients should be monitored for the development of signs and symptoms of infection during and after treatment with Erelzi, including the possible development of tuberculosis in patients who tested negative for latent tuberculosis infection prior to initiating therapy (see further detail in Serious and Opportunistic Infections section below).</td>
</tr>
</tbody>
</table>

**Malignancies**
- Lymphoma and other malignancies, some fatal, have been reported in children and adolescent patients treated with TNF blockers, including etanercept (see further detail in Malignancies/Pediatric Patients section below).
4  DOSAGE AND ADMINISTRATION

4.1  Dosing Considerations

Erelzi (etanercept) is intended for use under the guidance and supervision of a physician who has sufficient knowledge of RA, juvenile idiopathic arthritis, or ankylosing spondylitis and who has fully familiarized himself/herself with the efficacy/safety profile of Erelzi. Patients may self-inject only if their physician determines that it is appropriate and with medical follow-up, as necessary, after proper training in measurement of the correct dose and injection technique.

4.2  Recommended Dose and Dosage Adjustment

General
A 50 mg dose should be given as one subcutaneous (SC) injection. A 50 mg dose can also be given as two 25 mg SC injections.

When administering Erelzi as two 25 mg injections in adults or children, the injections should be given either on the same day once weekly or 3 or 4 days apart.

Adult RA and Ankylosing Spondylitis Patients
The recommended dose of Erelzi for adult patients with rheumatoid arthritis or ankylosing spondylitis is 50 mg per week. Methotrexate, glucocorticoids, salicylates, nonsteroidal anti-inflammatory drugs (NSAIDs), or analgesics may be continued during treatment with Erelzi. Based on a study of 50 mg etanercept twice weekly in patients with RA that suggested higher incidence of adverse reactions but similar American College of Rheumatology (ACR) response rates, doses higher than 50 mg per week are not recommended.

JIA Patients
The recommended dose of Erelzi for pediatric patients ages 4 to 17 years with active polyarticular JIA is 0.8 mg/kg per week (up to a maximum of 50 mg per week). Only pediatric patients weighing 63 kg (138 pounds) or more, who do not require weight-based dosing, can be treated with the Erelzi 50 mg prefilled syringe or the Erelzi 50 mg SensoReady® Pen. Patients weighing less than 63 kg should be accurately dosed on a mg/kg basis with other etanercept products.

Glucocorticoids, nonsteroidal anti-inflammatory drugs (NSAIDs), or analgesics may be continued during treatment with Erelzi. Concurrent use with methotrexate and higher doses of Erelzi have not been studied in pediatric patients.

4.3  Administration

Preparation of Erelzi Using the Single-use Prefilled Syringe or Single-use Prefilled SensoReady® Pen:
Before injection, allow Erelzi to reach room temperature (approximately 15 to 30 minutes). DO NOT remove the needle cap while allowing the prefilled syringe or SensoReady® Pen to reach room temperature.

Prior to administration, visually inspect the solution for particulate matter and discoloration. The liquid should be clear and colorless to slightly yellowish. You may see visible little particles, which is normal. DO NOT USE if the liquid is cloudy, discolored, or has large lumps, flakes, or colored particles.
Sites for injection include the front of thighs, lower abdomen, but not the area 2 inches around the navel; outer upper arm if caregiver/hcp is giving the injection. Injection sites should be rotated. New injections should be given at least one inch from an old site and never into areas where the skin is tender, bruised, red, or hard.

4.4 Missed Dose

Patients who miss a dose of Erelzi should be advised to contact their doctor to find out when to take their next dose of Erelzi.

5 OVERDOSAGE

The maximum tolerated dose of etanercept has not been established in humans. Toxicology studies have been performed in monkeys at doses up to 30 times the human dose with no evidence of dose-limiting toxicities. No dose-limiting toxicities have been observed during clinical trials of etanercept. Single IV doses up to 60 mg/m² have been administered to 32 healthy volunteers (25 males, 7 females) in an endotoxemia study without evidence of dose-limiting toxicities. The highest dose level evaluated in RA patients has been a single IV loading dose of 32 mg/m² followed by SC doses of 16 mg/m² (~25 mg) administered twice weekly. In one RA trial, one patient mistakenly self-administered 62 mg etanercept SC twice weekly for 3 weeks without experiencing adverse effects.

For management of a suspected drug overdose, contact your regional poison control centre immediately.

6 DOSAGE FORMS, STRENGTHS, COMPOSITION AND PACKAGING

For biologic products, including biosimilars, to help ensure the traceability of a specific product, health professionals should give consideration to recording both the brand name and the batch/lot number of the product supplied.

Erelzi single-use prefilled syringes with Needle Guard with finger flange are available in 25 mg (0.5 mL of a 50 mg/mL solution of etanercept) and 50 mg (1.0 mL of a 50 mg/mL solution of etanercept) dosage strength.

The Erelzi pre-filled syringe/SensoReady® pen has a removable rubber needle cap.

**Erelzi Single-use Prefilled SensoReady® Pen** is available in 50 mg (1.0 mL of a 50 mg/mL solution of etanercept) dosage strength.

Prefilled syringes and **SensoReady® Pens** are intended for subcutaneous injection.
The solution of Erelzi is clear and colorless to slightly yellowish, sterile, preservative free, and is formulated at pH 6.3 ± 0.2. There may be small white particles of protein in the solution.

Erelzi 25 mg and 50 mg single-use prefilled syringes and Erelzi 50 mg single-use prefilled SensoReady® Pen are supplied in cartons containing one, two, four or Multi-Packs of twelve syringes or prefilled pens with 27-gauge, ½ inch needles.

Administration of one 50 mg Erelzi prefilled syringe with Needle Guard or one Erelzi SensoReady® Pen provides a dose equivalent to two 25 mg Erelzi prefilled syringes with Needle Guard with finger flange.

7 DESCRIPTION

Erelzi (etanercept) is a dimeric fusion protein consisting of the extracellular ligand-binding portion of the human 75 kilodalton (p75) tumour necrosis factor receptor (TNFR) linked to the Fc portion of human immunoglobulin (IgG1). Etanercept is produced by recombinant DNA technology in a Chinese hamster ovary (CHO) mammalian cell expression system. It consists of 934 amino acids and has an apparent molecular weight of approximately 150 kilodaltons.

8 WARNINGS AND PRECAUTIONS

Please see the Serious Warnings and Precautions Box at the beginning of Part I: Health Professional Information.

Serious and Opportunistic Infections

Serious and sometimes fatal infections due to bacterial, mycobacterial, invasive fungal, viral, parasitic (including protozoal), or other opportunistic pathogens have been reported in patients receiving TNF-blocking agents. Tuberculosis, histoplasmosis, aspergillosis, blastomycosis, candidiasis, coccidioidomycosis, legionellosis, listeriosis, and pneumocystosis have been reported (see ADVERSE REACTIONS/Infections section). Patients have frequently presented with disseminated rather than localized disease. Many of the serious infections have occurred in patients on concomitant immunosuppressive therapy that, in addition to their underlying disease, could predispose them to infections.
Treatment with Erelzi should not be initiated in patients with an active infection, including clinically important localized infections. The risks and benefits of treatment should be considered prior to initiating therapy in patients:

- With chronic or recurrent infection;
- Who have been exposed to tuberculosis;
- With a history of an opportunistic infection;
- Who have resided or traveled in areas of endemic tuberculosis or mycoses, such as histoplasmosis, coccidiodomycosis, or blastomycosis;
- With underlying conditions that may predispose them to infection such as advanced or poorly controlled diabetes.

Cases of reactivation of tuberculosis or new tuberculosis infections have been observed in patients receiving etanercept, including patients who have previously received treatment for latent or active tuberculosis. Patients should be evaluated according to the Canadian Tuberculosis Standards guidelines for tuberculosis risk factors and tested for latent infection prior to initiating Erelzi and during therapy as appropriate. Prescribers are reminded of the risk of false negative tuberculin skin test results, especially in patients who are severely ill or immuno-compromised.

If active tuberculosis is diagnosed, Erelzi therapy should not be initiated. If inactive ('latent') tuberculosis is diagnosed, treatment for latent TB should be started with anti-tuberculosis therapy before the initiation of Erelzi. In this situation, the benefit/risk balance of Erelzi therapy should be very carefully considered. Anti-tuberculosis therapy should also be considered prior to initiation of Erelzi in patients with a past history of latent or active tuberculosis in whom an adequate course of treatment cannot be confirmed, and for patients with a negative test for latent tuberculosis but having risk factors for tuberculosis infection. Consultation with a physician with expertise in the treatment of tuberculosis is recommended to aid in the decision whether initiating anti-tuberculosis therapy is appropriate for an individual patient.

Patients should be monitored for the development of signs and symptoms of infection during and after treatment with Erelzi, including the possible development of tuberculosis in patients who tested negative for latent tuberculosis infection prior to initiating therapy. Tests for latent tuberculosis infection may be falsely negative while on therapy with Erelzi.

Tuberculosis should be strongly considered in patients who develop a new infection during Erelzi treatment, especially in patients who have previously or recently traveled to countries with a high prevalence of tuberculosis, or who have had close contact with a person with active tuberculosis.

Histoplasmosis and other invasive fungal infections are not consistently recognized in patients taking TNF blockers, including etanercept. This has resulted in delays in appropriate treatment, sometimes resulting in death. For patients who reside or travel in regions where mycoses are endemic, invasive fungal infection should be suspected if they develop a serious systemic illness. Appropriate empiric antifungal therapy may be initiated while a diagnostic workup is being performed. Antigen and antibody testing for histoplasmosis may be negative in some patients with active infection. When feasible, the decision to administer empiric antifungal therapy in these patients should be made in
consultation with a physician with expertise in the diagnosis and treatment of invasive fungal infections and taking into account both the risk for severe fungal infection and the risks of antifungal therapy.

Erelzi should be discontinued if a patient develops a serious infection or sepsis. A patient who develops a new infection during treatment with Erelzi should be closely monitored, undergo a prompt and complete diagnostic workup appropriate for an immunocompromised patient, and antimicrobial therapy should be initiated, as appropriate.

In post-marketing studies of patients with juvenile idiopathic arthritis, serious infections have been reported in approximately 3% of patients. Sepsis has also been reported in the post-market setting (0.8%).

**Neurologic Events**

Treatment with TNF blocking agents, including etanercept, has been associated with rare cases of new onset or exacerbation of central nervous system disorders, including demyelinating disorders, some presenting with mental status changes and some associated with permanent disability, and with peripheral nervous system demyelinating disorders. Rare cases of transverse myelitis, optic neuritis, and new onset or exacerbation of seizure disorders have been observed in association with etanercept therapy. Guillain-Barré like syndromes have been reported very rarely in postmarketing experience with etanercept therapy. While no clinical trials have been performed evaluating etanercept therapy in patients with multiple sclerosis, other TNF antagonists administered to patients with multiple sclerosis have been associated with increases in disease activity. Prescribers should exercise caution in considering the use of Erelzi in patients with pre-existing or recent-onset central or peripheral nervous system demyelinating disorders. Development of new, confirmed central nervous system demyelination in patients on Erelzi warrants consideration of discontinuation of the medication.

**Hematologic Events**

Rare cases (less than 1 case out of 1000 patients treated) of neutropenia, leukopenia, thrombocytopenia, anemia and pancytopenia (including aplastic anemia), some with fatal outcomes, have been reported in patients treated with etanercept. Cases of pancytopenia occurred as early as two weeks after initiating etanercept therapy. The causal relationship to etanercept therapy remains unclear. While the majority of patients who developed pancytopenia had recent or concurrent exposure to other anti-rheumatic medications known to be associated with myelosuppression (e.g., methotrexate, leflunomide, azathioprine, and cyclophosphamide), some patients had no recent or concurrent exposure to such therapies. Although no high risk group has been identified, caution should be exercised in patients being treated with Erelzi who have a previous history of significant hematologic abnormalities. All patients should be advised to seek immediate medical attention if they develop signs and symptoms suggestive of blood dyscrasias or infection (eg, persistent fever, bruising, bleeding, pallor) while on Erelzi. Discontinuation of Erelzi therapy should be considered in patients with confirmed significant hematologic abnormalities.

Patients treated with anakinra plus etanercept (3/139, 2%) developed neutropenia (ANC < 1 x 10^9/L). While neutropenic, one of these patients developed cellulitis that resolved with antibiotic therapy.
Malignancies

Lymphomas
In the controlled portions of clinical trials of all the TNF-blocking agents, more cases of lymphoma have been observed among patients receiving the TNF blocker compared to control patients. In the controlled and open-label portions of clinical trials of etanercept in RA and AS patients, the observed rate of lymphoma was 0.10 cases per 100 patient-years. This is 3-fold higher than expected in the general population. Patients with rheumatoid arthritis or psoriasis, particularly those with highly active disease and/or chronic exposure to immunosuppressant therapies, may be at a higher risk (up to several fold) for the development of lymphoma.

Postmarketing cases of hepatosplenic T-cell lymphoma (HSTCL), a rare type of T-cell lymphoma that has a very aggressive disease course and is usually fatal, have been reported in patients treated with TNF-blockers. The majority of reported TNF-blocker cases occurred in adolescent and young adult males with Crohn's disease or ulcerative colitis. Almost all of these patients had received treatment with the immunosuppressants azathioprine and/or 6-mercaptopurine concomitantly with a TNF-blocker at or prior to diagnosis.

Leukemia
Cases of acute and chronic leukemia have been reported in association with post-marketing TNF-blocker use in rheumatoid arthritis and other indications. Even in the absence of TNF-blocker therapy, patients with rheumatoid arthritis may be at higher risk (approximately 2-fold) than the general population for the development of leukemia.

During the controlled portions of etanercept trials, 2 cases of leukemia were observed among 5445 (0.06 cases per 100 patient-years) etanercept-treated patients versus 0 among 2890 (0%) control patients (duration of controlled treatment ranged from 3 to 48 months).

Among 15,401 patients treated with etanercept in controlled and open portions of clinical trials representing approximately 23,325 patient-years of therapy, the observed rate of leukemia was 0.03 cases per 100 patient-years (see ADVERSE REACTIONS/Clinical Trial Adverse Drug Reactions/Malignancies).

Other Malignancies
For malignancies other than lymphoma and non-melanoma skin cancer, there was no difference in exposure-adjusted rates between the etanercept and control arms in the controlled portions of clinical studies for all indications. Analysis of the malignancy rate in combined controlled and uncontrolled portions of studies has demonstrated that types and rates are similar to what is expected in the general population based on the SEER database and suggest no increase in rates over time.

Whether treatment with etanercept might influence the development and course of malignancies in adults is unknown (see ADVERSE REACTIONS/Clinical Trial Adverse Drug Reactions/Malignancies).

Melanoma and Non-melanoma skin cancer (NMSC)
Melanoma and non-melanoma skin cancer (NMSC) have been reported in patients treated with TNF-antagonists, including etanercept. In controlled and open portions of clinical trials among 15,401 patients treated with etanercept representing approximately 23,325 patient-years of therapy, the observed rate of melanoma was 0.043 cases per 100 patient-years. In controlled clinical trials of rheumatology (including RA and AS) patients, the observed rate of NMSC was
0.41 cases per 100 patient-years in the etanercept-treated patients compared to 0.37 cases per 100 patient-years among control patients. Post-marketing cases of Merkel cell carcinoma have been reported very infrequently in patients treated with etanercept.

Risk factors for melanoma or NMSC include cumulative exposure to ultraviolet light, increasing age, male gender, fair complexion, history of acute sunburn or skin cancer, tobacco use, and immunosuppressive agents. Periodic skin examination should be considered for all patients at increased risk for skin cancers.

**Pediatric Patients**
Malignancies, some fatal, have been reported among children, adolescents and young adults (≤ 22 years of age) who initiated treatment with TNF-blocking agents (initiation of therapy at ≤ 18 years of age), including etanercept. These cases were reported post-marketing and are derived from a variety of sources including registries and spontaneous post-marketing reports. Approximately half the cases were lymphomas, including Hodgkin’s and non-Hodgkin’s lymphoma. Of these cases, hepatosplenic T-cell lymphoma was not reported in patients treated with etanercept. The other cases represented a variety of different malignancies and included rare malignancies usually associated with immunosuppression and malignancies that are not usually observed in children and adolescents. Approximately half of these malignancies occurred in patients being treated for inflammatory bowel disease; approximately one-third of the cases occurred in patients being treated for JIA. The malignancies occurred after a median of 30 months of therapy (range 1 to 84 months). Most of the patients were receiving concomitant immunosuppressants.

In clinical trials of 696 patients treated with etanercept, representing 1282 patient-years of therapy, no malignancies, including lymphoma or NMSC, have been reported.

**Wegener’s Granulomatosis**
In a randomized placebo controlled study of 180 patients with Wegener’s granulomatosis, the addition of etanercept to standard treatment (including cyclophosphamide, methotrexate, and corticosteroids) was no more efficacious than standard therapy alone. Patients receiving etanercept experienced more non-cutaneous malignancies than patients receiving placebo. The role of etanercept in this finding is uncertain due to imbalances between the two arms of the study including age, disease duration, and use of cyclophosphamide. The use of etanercept in patients with Wegener’s granulomatosis receiving immunosuppressive agents is not recommended. The use of etanercept in any patients receiving concurrent cyclophosphamide therapy is not recommended.

**General**
Parenteral administration of any biologic product should be attended by appropriate precautions in case an allergic or untoward reaction occurs. Allergic reactions associated with administration of Erelzi during clinical trials have been reported in < 2% of patients. If any serious allergic or anaphylactic reaction occurs, administration of Erelzi should be discontinued immediately and appropriate therapy initiated.

**Concurrent etanercept and anakinra treatment**
Serious infections and neutropenia were seen in clinical studies with concurrent use of anakinra and etanercept with no added clinical benefit compared to etanercept alone. Because of the nature of the adverse events seen with combination of etanercept and anakinra therapy, the combination of etanercept and anakinra is not recommended (see DRUG INTERACTIONS).
Concurrent etanercept and abatacept treatment
In clinical studies, concurrent administration of abatacept and etanercept resulted in increased incidences of serious adverse events and did not demonstrate increased clinical benefit. Use of etanercept with abatacept is not recommended (see DRUG INTERACTIONS).

Switching between Biological DMARDS
When switching from one biologic to another, patients should continue to be monitored for signs of infection.

Surgery
There is limited safety experience of surgical procedures in patients treated with etanercept. The half-life of etanercept should be taken into consideration if a surgical procedure is planned. A patient who requires surgery while on Erelzi should be closely monitored for infections, and appropriate actions should be taken.

Cardiovascular
Two large clinical trials (2048 patients) evaluating the use of etanercept in the treatment of heart failure were terminated early due to lack of efficacy. There was a suggestion of worse heart failure outcomes in patients with moderate to severe CHF (NYHA Class III/IV) receiving etanercept treatment compared to patients receiving placebo in one of the two trials. There have been post-marketing reports of worsening of congestive heart failure (CHF), with and without identifiable precipitating factors, in patients taking etanercept. Physicians should exercise caution when using Erelzi in patients who also have CHF, particularly NYHA Class III/IV.

Immune
Immunosuppression and Immunocompetence
The possibility exists for anti-TNF therapies, including etanercept, to affect host defenses against infections and malignancies since TNF mediates inflammation and modulates cellular immune responses. In a study of 49 patients with RA treated with etanercept, there was no evidence of depression of delayed-type hypersensitivity, depression of immunoglobulin levels, or change in enumeration of effector cell populations. The role of etanercept in the development and course of malignancies as well as active and/or chronic infections is not fully understood. The safety and efficacy of etanercept in patients with immunosuppression or chronic infections have not been evaluated.

Immunizations
Live vaccines (including yellow fever, BCG, rubella, polio, cholera, typhoid and varicella) should not be given concurrently with etanercept. No data are available on the secondary transmission of infection by live vaccines in patients receiving etanercept. No data are available on the effects of vaccination in RA patients receiving etanercept.

It is recommended that JIA patients, if possible, be brought up to date with all immunizations in agreement with current immunizations guidelines prior to initiating Erelzi therapy. Two JIA patients developed varicella infection and signs and symptoms of aseptic meningitis, which resolved without sequelae. Patients with a significant exposure to varicella virus should temporarily discontinue Erelzi therapy and be considered for prophylactic treatment with Varicella Zoster Immune Globulin.

Autoimmunity
Treatment with etanercept may result in the formation of autoantibodies and, rarely, can result in
the development of lupus-like syndrome or autoimmune hepatitis, which may resolve following withdrawal of etanercept. If a patient develops symptoms and findings suggestive of a lupus-like syndrome or autoimmune hepatitis following treatment with Erelzi, treatment should be discontinued and the patient should be carefully evaluated.

**Hepatic**

**Hepatitis B Reactivation**

Reactivation of hepatitis B in patients who were previously infected with the hepatitis B virus (HBV) and had received concomitant TNF antagonists, including very rare cases with etanercept, has been reported. In the majority of cases, patients were also being treated with other immunosuppressive drugs, including methotrexate, azathioprine, and/or corticosteroids. Hepatitis B reactivation is not unique to TNF antagonists and has been reported with other immunosuppressive drugs. Therefore, a direct causal relationship to TNF antagonists has not been established. Patients should be evaluated for prior evidence of HBV infection before initiating TNF antagonist therapy. Those previously infected with HBV should be monitored for signs and symptoms of active HBV infection throughout the course of therapy and for several months following discontinuation of therapy.

**Use in Patients with Moderate to Severe Alcoholic Hepatitis**

Physicians should use caution when using Erelzi in patients with moderate to severe alcoholic hepatitis. In a study of 48 hospitalized patients treated with etanercept or placebo for moderate to severe alcoholic hepatitis, the mortality rate in patients treated with etanercept was similar to patients treated with placebo at one month but significantly higher after six months. Therefore, the use of Erelzi for the treatment of patients with alcoholic hepatitis is not recommended.

**Carcinogenesis, Mutagenesis, and Impairment of Fertility**

Long-term animal studies have not been conducted to evaluate the carcinogenic potential of etanercept or its effect on fertility. Mutagenesis studies were conducted in vitro and in vivo, and no evidence of mutagenic activity was observed.

### 8.1 Special Populations

#### 8.1.1 Pregnant Women

**Pregnant Women:**

There have been no studies in pregnant women. Erelzi should not be used during pregnancy unless benefits outweigh the risks (see ADVERSE REACTIONS and WARNINGS AND PRECAUTIONS). Etanercept has no established use in labour or delivery.

Developmental toxicity studies have been performed in rats and rabbits at doses ranging from 60- to 100-fold higher than the human dose and have revealed no evidence of harm to the fetus due to etanercept. Because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Etanercept crosses the placenta and has been detected in the serum of infants born to women treated with etanercept during pregnancy. The clinical impact of this exposure is unknown; however, infants may be at increased risk of infection. Administration of live vaccines to infants for 16 weeks after the mother’s last dose of etanercept is generally not recommended.
8.1.2 Breast-feeding

Nursing Women:
Etanercept has been reported to be excreted in human milk following subcutaneous administration. Because many drugs and immunoglobulins can be excreted in human milk, and because of the potential of serious adverse reactions in nursing infants from etanercept, a decision should be made whether to discontinue nursing or to discontinue the drug.

8.1.3 Pediatrics

Pediatrics:
Etanercept is indicated for treatment of polyarticular juvenile idiopathic arthritis in patients who have had an inadequate response to one or more DMARDs. In post-marketing studies with juvenile idiopathic arthritis, serious infections have been reported in approximately 3% of patients. Sepsis has also been reported in the post-market setting (0.8%). The long-term effects of etanercept therapy on skeletal, behavioral, cognitive, sexual and immune maturation and development in children are unknown.

A higher rate of adverse events was noted when juvenile idiopathic arthritis patients in an observational registry received etanercept therapy in combination with methotrexate. As the juvenile idiopathic arthritis patients receiving combination therapy had more severe disease, since they had failed prior therapeutic trials with either etanercept or methotrexate alone, it remains unclear whether the higher event rate is related to therapy or underlying disease severity.

There have been reports of Inflammatory Bowel Disease (IBD) in juvenile idiopathic arthritis (JIA) patients receiving etanercept, which is not effective for the treatment of IBD. A causal relationship with etanercept is unclear because clinical manifestations of bowel inflammation have also been observed in untreated JIA patients.

Etanercept has not been studied in children < 2 years of age.

8.1.4 Geriatrics

Geriatrics (> 65 years of age):
Four hundred and eighty clinical study patients in RA were age 65 or older. No overall differences in safety or effectiveness were observed between these patients and younger patients.

Greater sensitivity of some older individuals cannot be ruled out. Predisposition of older individuals to infection justifies greater caution when treating the elderly.

Use in Diabetics:
There have been reports of hypoglycemia following initiation of etanercept in patients receiving medication for diabetes, necessitating a reduction in anti-diabetic medication in some of these patients.
9 ADVERSE REACTIONS

The adverse drug reaction profiles reported in clinical studies that compared Erelzi to the reference biologic drug were comparable. The description of adverse reactions in this section is based on clinical experience with the reference biologic drug.

9.1 Adverse Reaction Overview

Adverse Reactions in Adult Patients with RA or Ankylosing Spondylitis
Etanercept has been studied in 1442 patients with RA who have been followed for over 6 years, including 225 patients who have been followed for more than 10 years. Etanercept has been studied in 222 patients with ankylosing spondylitis for up to 48 months. Etanercept has over four million patient-years of post-market exposure.

Among patients with RA treated in placebo-controlled studies, serious adverse events occurred at a frequency of 4% in 349 patients treated with etanercept compared to 5% of 152 placebo-treated patients. In a subsequent study (Study III), serious adverse events occurred at a frequency of 6% in 415 patients treated with etanercept compared to 8% of 217 methotrexate-treated patients. In long-term open-label studies in adults with RA, there were no new or unexpected serious adverse events reported.

Among RA patients in placebo-controlled, active-controlled, and open-label trials of etanercept, infections and malignancies were the most common serious adverse events observed. Other infrequent serious adverse events observed in RA or ankylosing spondylitis clinical trials are listed below by body system:

- Cardiovascular: cardiomyopathy, fainting, heart failure, hypertension, hypotension, myocardial infarction, myocardial ischemia, deep vein thrombosis, thrombophlebitis
- Digestive: cholecystitis, diarrhea, esophageal ulcer, gastrointestinal hemorrhage, pancreatitis, appendicitis
- General: impaired healing, asthenia
- Hematologic/Lymphatic: lymphadenopathy, myelodysplastic syndrome, necrotizing granulomatous lymphadenitis
- Hepatic: hepatic disorder, hepatic steatosis
- Musculoskeletal: bursitis, fistula, fracture nonunion, polymyositis
- Nervous: anxiety, cerebral ischemia, convulsion, depression, multiple sclerosis
- Respiratory: asthma, dyspnea, pulmonary embolism, sarcoidosis
- Skin: worsening psoriasis
- Urogenital: membranous glomerulonephropathy, kidney calculus
In a randomized controlled trial in which 51 patients with RA received etanercept 50 mg twice weekly and 25 patients received etanercept 25 mg twice weekly, the following serious adverse events were observed in the 50 mg twice weekly arm: gastrointestinal bleeding, normal pressure hydrocephalus, seizure, and stroke. No serious adverse events were observed in the 25 mg arm.

In controlled trials, the proportion of patients who discontinued treatment due to adverse events was approximately 4% in both the etanercept and placebo treatment groups. The vast majority of these patients were treated with the recommended dose of 25 mg SC twice weekly. Among patients with rheumatoid arthritis in placebo-controlled studies, deaths occurred in 10 of 2696 (0.37%) etanercept-treated patients compared to 3 of 1167 (0.26%) placebo-treated patients. In controlled and uncontrolled RA studies there were 58 deaths in 6973 patient treated with at least one dose of etanercept over an exposure period of 11,765 patient-years (exposure-adjusted rate of 0.49). In the long-term open-label RA studies, the rate of death did not increase over time with increasing exposure to etanercept. No deaths were reported in AS or JIA studies.

9.2 Clinical Trial Adverse Reactions

Because clinical trials are conducted under very specific conditions, the adverse reaction rates observed in the clinical trials may not reflect the rates observed in practice and should not be compared to the rates in the clinical trials of another drug. Adverse reaction information from clinical trials is useful for identifying drug-related adverse events and for approximating rates.

Adverse reactions reported in at least 1% of all patients who received etanercept in placebo-controlled RA trials (including the combination methotrexate trial) are outlined in Table 1 below. Adverse reactions reported in juvenile idiopathic arthritis and ankylosing spondylitis trials were similar to those reported in RA clinical trials.

9.3 Less Common Clinical Trial Adverse Reactions

Less Common Clinical Trial Adverse Drug Reactions (< 1%)

The following adverse reactions were reported at an incidence of < 1% (occurring in more than 1 patient, with higher frequency than placebo): Body as a Whole: enlarged abdomen, general edema, hernia, infection, injection site reaction, malaise, overdose, Sjogrens syndrome; 
Cardiovascular: cerebrovascular accident, hypotension, myocardial infarction, phlebitis, deep thrombophlebitis; Gastrointestinal: increased appetite, colitis, dysphagia, glossitis, gum hemorrhage, rectal hemorrhage; 
Hemic and Lymphatic System: petechia; 
Metabolic and Nutritional Disorders: edema, hypercholesteremia, hyperglycemia; Musculoskeletal System: arthrosis, bone disorder, fibrosis tendon, bone necrosis; Nervous System: nervousness, neuropathy; Respiratory System: bronchitis, lung carcinoma, hemoptysis, laryngitis; 
Skin and Appendages: skin carcinoma, dermatitis exfoliative, skin hypertrophy, skin discolouration, skin ulcer; Special Senses: corneal lesion, ear disorder, eye hemorrhage, otitis media; 
Urogenital System: cervix disorder, cystitis, dysuria, gynecomastia, uterine hemorrhage, kidney polycystic, cervix neoplasm, polyuria, urine urgency.

Injection Site Reactions

In controlled trials in rheumatologic indications, approximately 37% of patients treated with etanercept developed injection site reactions. All injection site reactions were described as mild to moderate (erythema and/or itching, pain, or swelling). Injection site reactions generally occurred in the first month, if they occurred at all, did not necessitate study drug discontinuation, and subsequently decreased in frequency after the first month. The mean duration was 3 to 5
days. No treatment was given for approximately 90% of injection site reactions, and most of the patients who were given treatment received topical preparations, such as corticosteroids, or oral antihistamines. There have been common occurrences (7%) of redness at a previous injection site when subsequent injections were given; however, no intervention was necessary. In post-marketing experience, there have been reported cases (1.8% of all patients treated) of injection site bleeding and bruising observed in conjunction with etanercept therapy.

**Infections**
The percent of patients reporting infections in controlled studies of etanercept in rheumatoid arthritis and ankylosing spondylitis is provided in Table 2. The most common type of infection was upper respiratory infection.

*Fisher’s exact p-value < 0.05

For dose and regimen of Etanercept in each indication, please refer to Part II Clinical Trials section.

In placebo-controlled trials in RA and ankylosing spondylitis no increase in the incidence of serious infections was observed (approximately 1% in both placebo- and Etanercept-treated groups). In all clinical trials in RA, serious infections experienced by patients have included pyelonephritis, bronchitis, septic arthritis, abdominal abscess, cellulitis, osteomyelitis, wound infection, pneumonia, foot abscess, leg ulcer, diarrhea, sinusitis and sepsis. The rate of serious infections has not increased in open-label extension trials and is similar to that observed in controlled trials (Table 3). Serious infections, including sepsis and death, have also been reported during post-marketing use of etanercept. Some have occurred within a few weeks after initiating treatment with etanercept. Many of the patients had underlying conditions (e.g., diabetes, congestive heart failure, history of active or chronic infections) in addition to their RA. Data from a sepsis clinical trial not specifically in patients with RA suggest that etanercept treatment may increase mortality in patients with established sepsis.

\*Controlled trials and open-label extension studies in RA.

In a controlled trial in patients with ankylosing spondylitis, rates of infection were also similar to those observed in the controlled studies of patients with RA. No increase in the incidence of serious infections was observed in patients treated with etanercept.

In 2 studies in which patients were receiving both etanercept and anakinra for up to 24 weeks, the incidence of serious infections was 7%. The most common infections consisted of bacterial pneumonia (4 cases) and cellulitis (4 cases). One patient with pulmonary fibrosis and pneumonia died due to respiratory failure.

In global etanercept clinical studies of 20,070 patients (28,308 patient-years of therapy), tuberculosis was observed in approximately 0.01% of patients. In 15,438 patients (23,524 patient-years of therapy) from clinical studies in the US and Canada, tuberculosis was observed in approximately 0.007% of patients. These studies include reports of pulmonary and extra-pulmonary tuberculosis (see WARNINGS and PRECAUTIONS/Serious and Opportunistic Infections section).

In 38 etanercept clinical trials and 4 cohort studies in all approved indications representing 27,169 patient-years of exposure (17,696 patients) from the United States and Canada, no histoplasmosis infections were reported among patients treated with etanercept. Data from clinical studies and post-marketing reports suggest that differences may exist in the risk of invasive histoplasmosis infection among TNF blockers. Nonetheless, post-marketing cases of serious and sometimes fatal fungal infections, including histoplasmosis, have been reported with TNF blockers, including etanercept (see WARNINGS and PRECAUTIONS/Serious and Opportunistic Infections section).

In post-marketing experience infections have been observed with various pathogens including viral, bacterial, mycobacterial, invasive fungal, and parasitic (including protozoal) organisms. Infections, including opportunistic infections (including atypical mycobacterial infection, herpes
zoster, aspergillosis, *Pneumocystis jiroveci* pneumonia, histoplasmosis, candidiasis, coccidioidomycosis, listeriosis and legionellosis), have been reported in patients receiving etanercept alone or in combination with immunosuppressive agents.

**Malignancies**

Information is available from 10,953 adult patients with 17,123 patient-years and 696 pediatric patients with 1282 patient-years of experience across 45 etanercept clinical studies.

In an open-label extension study that followed 581 DMARD-refractory RA patients for more than 10 years, the standardized incidence ratio (SIR) for all malignancies with respect to corresponding SEER rate was 1.30 with the 95% confidence interval (CI) of 0.97 to 1.71. In an open-label extension study that followed 468 early active RA patients for up to 9.6 years, the SIR for all malignancies with respect to corresponding SEER rate was 1.39 with the 95% CI of 0.98 to 1.93.

**Lymphomas**

An increased rate of lymphoma up to several-fold has been reported in the RA patient population, and may be further increased in patients with more severe disease activity.

In the controlled portions of clinical trials of TNF-blocking agents, more cases of lymphoma have been observed among patients receiving a TNF blocker compared to control patients. During the controlled portions of etanercept trials in adult patients including those with RA and AS, 2 lymphomas were observed among 3306 etanercept-treated patients versus 0 among 1521 control patients (duration of controlled treatment ranged from 3 to 36 months).

Among 6543 adult rheumatology (including RA and AS) patients treated with etanercept in controlled and uncontrolled portions of clinical trials, representing approximately 12,845 patient-years of therapy, the observed rate of lymphoma was 0.10 cases per 100 patient-years. This was 3-fold higher than the rate of lymphoma expected in the general population based on the SEER database.

In an open-label extension study that followed 581 DMARD-refractory RA patients for more than 10 years, the SIR for lymphomas with respect to corresponding SEER rate was 4.49 with a 95% CI of 1.81 to 9.26. In an open-label extension study that followed 468 early active RA patients for up to 9.6 years, the SIR for lymphomas with respect to corresponding SEER rate was 7.76 with a 95% CI of 3.35 to 15.30.

**Leukemia**

Cases of acute and chronic leukemia have been reported in association with post-marketing TNF-blocker use in rheumatoid arthritis and other indications. Even in the absence of TNF-blocker therapy, patients with rheumatoid arthritis may be at higher risk (approximately 2-fold) than the general population for the development of leukemia.

During the controlled portions of etanercept trials, 2 cases of leukemia were observed among 5445 (0.06 cases per 100 patient-years) etanercept-treated patients versus 0 among 2890 (0%) control patients (duration of controlled treatment ranged from 3 to 48 months).

Among 15,401 patients treated with etanercept in controlled and open portions of clinical trials representing approximately 23,325 patient-years of therapy, the observed rate of leukemia was 0.03 cases per 100 patient-years.
Other Malignancies
For malignancies other than lymphoma and non-melanoma skin cancer, there was no difference in exposure-adjusted rates between the etanercept and control arms in the controlled portions of clinical studies for all indications. Analysis of the malignancy rate in combined controlled and uncontrolled portions of studies has demonstrated that types and rates are similar to what is expected in the general population based on the SEER database and suggest no increase in rates over time.

Whether treatment with etanercept might influence the development and course of malignancies in adults is unknown.

Melanoma and Non-melanoma skin cancer (NMSC)
Melanoma and non-melanoma skin cancer (NMSC) have been reported in patients treated with TNF-antagonists, including etanercept. Among 15,401 patients treated with etanercept in controlled and open portions of clinical trials representing approximately 23,325 patient-years of therapy, the observed rate of melanoma was 0.043 cases per 100 patient-years. Among 3306 adult rheumatology (including RA and AS) patients treated with etanercept in controlled clinical trials, representing approximately 2669 patient-years of therapy, the observed rate of NMSC was 0.41 cases per 100 patient-years vs. 0.37 cases per 100 patient-years among 1521 control patients representing 1077 patient-years.

Among 89 patients with Wegener’s granulomatosis receiving etanercept in a randomized, placebo-controlled trial, 5 experienced a variety of non-cutaneous solid malignancies compared with none receiving placebo (see WARNINGS AND PRECAUTIONS/ Wegener’s granulomatosis).

Autoantibodies
Patients had serum samples tested for autoantibodies at multiple time points. In RA Studies I and II, the percentage of patients evaluated for antinuclear antibodies (ANA) who developed new positive ANA (1:40) was higher in patients treated with etanercept (11%) than in placebo-treated patients (5%). The percentage of patients who developed new positive anti-double-stranded DNA antibodies was also higher by radioimmunoassay (15% of patients treated with etanercept compared to 4% of placebo-treated patients) and by Crithidia luciliae assay (3% of patients treated with etanercept compared to none of placebo-treated patients). The proportion of patients treated with etanercept who developed anticardiolipin antibodies was similarly increased compared to placebo-treated patients. In Study III, no pattern of increased autoantibody development was seen in etanercept patients compared to methotrexate patients.

The impact of long-term treatment with etanercept on the development of autoimmune diseases is unknown. Rare adverse event reports have described patients with rheumatoid factor positive and/or erosive RA who have developed additional autoantibodies in conjunction with rash and other features suggesting a lupus-like syndrome.

Immunogenicity
Patients with RA or ankylosing spondylitis were tested at multiple time points for antibodies to etanercept. Non-neutralizing antibodies to the TNF receptor portion or other protein components of the etanercept drug product were detected at least once in sera of approximately 6% of adult patients with RA or ankylosing spondylitis. Results from JIA patients were similar to those seen in adult RA patients treated with etanercept. In all clinical studies with etanercept to date, there has been no apparent correlation of antibody development to clinical response or adverse events. Neutralizing antibodies have not been observed with etanercept.
The data reflect the percentage of patients whose test results were considered positive for antibodies to etanercept in an ELISA assay and are highly dependent on the sensitivity and specificity of the assay. Additionally, the observed incidence of any antibody positivity in an assay is highly dependent on several factors including assay sensitivity and specificity, assay methodology, sample handling, timing of sample collection, concomitant medications, and underlying disease. For these reasons, comparison of the incidence of antibodies to etanercept with incidence of antibodies to other products may be misleading.

**Patients with Heart Failure**
Two randomized placebo-controlled studies have been performed in patients with CHF. In one study, patients received either etanercept 25 mg twice weekly, 25 mg three times weekly, or placebo. In a second study, patients received either etanercept 25 mg once weekly, 25 mg twice weekly, or placebo. Results of the first study suggested higher mortality in patients treated with etanercept at either schedule compared to placebo. Results of the second study did not corroborate these observations. Analyses did not identify specific factors associated with increased risk of adverse outcomes in heart failure patients treated with etanercept (see WARNINGS AND PRECAUTIONS/ Cardiovascular).

**9.4 Abnormal Laboratory Findings: Hematologic, Clinical Chemistry and Other Quantitative Data**

**Other**
In a study with etanercept manufactured by a modified process (see PART II/ CLINICAL TRIALS/ Other Studies) major adverse events included the following. Twelve patients (5.4%) experienced 13 serious adverse events. One patient experienced a benign lung neoplasm. One patient (0.4%) experienced a life-threatening non-infectious event (pulmonary embolism) and 14 patients (6.3%) experienced severe non-infectious adverse events. One serious event (urinary tract infection) was considered infectious. One adverse event of hepatic neoplasm malignant (serious) and one squamous cell carcinoma (non-serious) were reported. Overall, the safety profile was comparable to the etanercept manufactured using the previous process.

**9.5 Clinical Trial Adverse Reactions (Pediatrics)**

**Adverse Reactions in Pediatric Patients**
In general, the adverse events in pediatric patients were similar in frequency and type as those seen in adult patients. Differences from adult and other special considerations are discussed in the following paragraphs.

Severe adverse reactions reported in 69 JIA patients ages 4 to 17 years included varicella, gastroenteritis, depression/personality disorder, cutaneous ulcer, esophagitis/gastritis, group A streptococcal septic shock, type I diabetes mellitus, and soft tissue and post-operative wound infection.

Forty-three of 69 (62%) children with JIA experienced an infection while receiving etanercept during the 3 months of the study (part 1 open-label), and the frequency and severity of infections was similar in 58 patients completing 12 months of open-label extension therapy. The types of infections reported in JIA patients were generally mild and consistent with those commonly seen in outpatient pediatric populations.
The following adverse events were reported more commonly in 69 JIA patients receiving 3 months of etanercept compared to the 349 adult RA patients in placebo-controlled trials. These included headache (19% of patients, 1.7 events per patient-year), nausea (9%, 1.0 events per patient-year), abdominal pain (19%, 0.74 events per patient-year), and vomiting (13%, 0.74 events per patient-year).

In clinical studies of children with JIA, adverse events reported in those aged 2 to 4 years were similar to adverse events reported in older children.

In post-marketing experience, the following additional serious adverse events have been reported in pediatric patients: abscess with bacteremia, optic neuritis, pancytopenia, neutropenia, leukopenia, thrombocytopenia, anemia, seizures, tuberculous arthritis, urinary tract infection including urosepsis, coagulopathy, cutaneous vasculitis, bronchitis, gastroenteritis and transaminase elevation. Other significant adverse events have included depression. The frequency of these events and their causal relationship to etanercept therapy is unknown.

The long-term effects of etanercept therapy on skeletal, behavioral, cognitive, sexual and immune maturation and development in children are unknown.

A higher rate of adverse events was noted when JIA patients in an observational registry received etanercept therapy in combination with methotrexate. As the juvenile idiopathic arthritis patients receiving combination therapy had more severe disease, since they had failed prior therapeutic trials with either etanercept or methotrexate alone, it remains unclear whether the higher event rate is related to therapy or underlying disease severity.

9.6 Post-Market Adverse Reactions

Additional adverse events have been identified during post-marketing use of etanercept. Because these events are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to etanercept exposure. These adverse events include, but are not limited to, the following (listed by body system):

- **Body as a Whole:** angioedema, fatigue, fever, flu syndrome, generalized pain, weight gain
- **Cardiovascular:** chest pain, vasodilation (flushing), new-onset congestive heart failure
- **Digestive:** altered sense of taste, anorexia, diarrhea, dry mouth, intestinal perforation
- **Hematologic/Lymphatic:** adenopathy, anemia, aplastic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia
- **Hepatobiliary:** autoimmune hepatitis, elevated transaminase, hepatitis B reactivation
- **Immune:** macrophage activation syndrome, systemic vasculitis
- **Musculoskeletal:** joint pain, lupus-like syndrome with manifestations including rash consistent with subacute or discoid lupus
- **Neoplasms benign:** Merkel cell carcinoma
malignant and unspecified:

Nervous: paresthesias, stroke, seizures and central nervous system events suggestive of multiple sclerosis or isolated demyelinating conditions such as transverse myelitis or optic neuritis

Ocular: dry eyes, ocular inflammation, scleritis, uveitis

Respiratory: dyspnea, interstitial lung disease, pulmonary disease, worsening of prior lung disorder

Skin: cutaneous vasculitis, including leukocytoclastic vasculitis (with several symptom manifestations), erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis, pruritus, subcutaneous nodules, urticaria, new or worsening psoriasis (all subtypes including pustular and palmoplantar)

10 DRUG INTERACTIONS

10.1 Overview

Specific drug interaction studies have not been conducted with etanercept. Etanercept has not been formally evaluated in combination with other DMARDs such as gold, antimalarials, sulfasalazine, penicillamine, azathioprine, cyclophosphamide, or leflunomide and the benefits and risks of such combinations are unknown.

10.2 Drug-Drug Interactions

Etanercept can be used in combination with methotrexate in adult patients with rheumatoid arthritis.

No clinically significant pharmacokinetic drug-drug interactions were observed in studies with digoxin and warfarin.

A higher rate of adverse events was noted when juvenile idiopathic arthritis patients in an observational registry received etanercept therapy in combination with methotrexate. As the juvenile idiopathic arthritis patients receiving combination therapy had more severe disease, since they had failed prior therapeutic trials with either etanercept or methotrexate alone, it remains unclear whether the higher event rate is related to therapy or underlying disease severity.

Patients in a clinical study who were on established therapy with sulfasalazine, to which etanercept was added, experienced a statistically significant decrease in mean white blood cell counts in comparison to groups treated with either etanercept or sulfasalazine alone. The significance of this observation is unknown.

Concurrent introduction of etanercept and anakinra therapies has not been associated with increased clinical benefit to patients. In a study in which patients with active RA were treated for up to 24 weeks with concurrent etanercept and anakinra therapy, a 7% rate of serious infections
was observed, which was higher than that observed with etanercept alone (0%). Two percent of patients treated concurrently with etanercept and anakinra developed neutropenia (ANC < 1 x 10⁹/L).

In a study of patients with Wegener's granulomatosis, the addition of etanercept to standard therapy (including cyclophosphamide) was associated with a higher incidence of non-cutaneous malignancies. Although the role of etanercept in this finding is uncertain, the use of Erelzi in any patients receiving concurrent cyclophosphamide therapy is not recommended.

In clinical studies, concurrent administration of abatacept and etanercept resulted in increased incidences of serious adverse events and did not demonstrate increased clinical benefit. Use of Erelzi with abatacept is not recommended.

The drugs listed in this table are based on either drug interaction case reports or studies, or potential interactions due to the expected magnitude and seriousness of the interaction (i.e., those identified as contraindicated).

11 ACTION AND CLINICAL PHARMACOLOGY

11.1 Mechanism of Action

Erelzi (etanercept) is a dimeric fusion protein consisting of the extracellular ligand-binding portion of the human 75 kilodalton (p75) tumor necrosis factor receptor (TNFR) linked to the Fc portion of human IgG1. It consists of 934 amino acids and has an apparent molecular weight of approximately 150 kilodaltons.

Etanercept binds specifically to soluble and cell surface tumor necrosis factor (TNF) and blocks its interaction with cell surface TNF receptors. Etanercept inactivates TNF without causing in vitro lysis of cells involved in the immune response. TNF is a naturally occurring cytokine, or immune system protein, that is implicated in the development and progression of inflammatory, infectious, and autoimmune diseases. TNF plays an important role in the inflammatory processes of rheumatoid arthritis (RA), polyarticular juvenile idiopathic arthritis (JIA), ankylosing spondylitis and the resulting joint pathology. Elevated levels of TNF are found in the synovial fluid of RA patients and in serum and synovial tissue of patients with ankylosing spondylitis.

Two distinct receptors for TNF (TNFRs), a 55 kilodalton protein (p55) and a 75 kilodalton protein (p75), exist naturally as monomeric molecules on cell surfaces and in soluble forms. Biological activity of TNF is dependent upon binding to either cell surface TNFR. Etanercept is a dimeric soluble form of the p75 TNF receptor that can bind to two TNF molecules. This dimeric binding provides substantially greater competitive inhibition of TNF than monomeric soluble receptors.

Much of the joint pathology in RA is mediated by proinflammatory molecules that are linked in a network controlled by TNF.

Etanercept competitively inhibits binding of both TNF α and TNF β (lymphotoxin α [LT α]) to cell surface TNF receptors, rendering TNF biologically inactive. Etanercept does not cause lysis of TNF-producing cells in vitro, in the presence or absence of complement.
11.2 Pharmacodynamics

Etanercept also modulates biological responses that are induced or regulated by TNF, including expression of adhesion molecules responsible for leukocyte migration (i.e., E-selectin and to a lesser extent intercellular adhesion molecule-1 [ICAM-1]), serum levels of cytokines (e.g., IL-6, IL-1), and serum levels of matrix metalloproteinase-3 (MMP-3 or stromelysin). Etanercept has been shown to affect several animal models of inflammation, including murine collagen-induced arthritis.

11.3 Pharmacokinetics

After administration of 25 mg etanercept by a single subcutaneous (SC) injection to 25 patients with RA, a mean ± standard deviation half-life of 102 ± 30 hours was observed with a clearance of 160 ± 80 mL/hr. A maximum serum concentration (C\(_{\text{max}}\)) of 1.1 ± 0.6 mcg/mL and time to C\(_{\text{max}}\) of 69 ± 34 hours was observed in these patients following a single 25 mg dose. After 6 months of twice weekly 25 mg doses in these same RA patients, the mean C\(_{\text{max}}\) was 2.4 ± 1.0 mcg/mL (N = 23). Patients exhibited a two- to seven-fold increase in peak serum concentrations and approximately four-fold increase in AUC\(_{\text{0-72hr}}\) (range 1 to 17 fold) with repeated dosing. Serum concentrations in patients with RA have not been measured for periods of dosing that exceed 6 months.

In another study, serum concentration profiles at steady state were comparable among patients with RA treated with 50 mg etanercept once weekly and those treated with 25 mg etanercept twice weekly. The mean (± standard deviation) C\(_{\text{max}}\), C\(_{\text{min}}\), and partial AUC were 2.4 ± 1.5 mg/L, 1.2 ± 0.7 mg/L, and 297 ± 166 mg•h/L, respectively, for patients treated with 50 mg etanercept once weekly (N = 21); and 2.6 ± 1.2 mg/L, 1.4 ± 0.7 mg/L, and 316 ± 135 mg•h/L for patients treated with 25 mg etanercept twice weekly (N = 16).

Special Populations and Conditions

*Pediatrics:* Pediatric patients with JIA (ages 4 to 17 years) were administered 0.4 mg/kg of etanercept twice weekly (up to a maximum dose of 50 mg per week) for up to 18 weeks. The average serum concentration after repeated dosing was 2.1 mcg/mL, with a range of 0.7 to 4.3 mcg/mL compared to a serum concentration of 3.1 mcg/mL, with a range of 0.9 to 5.6 mcg/mL in adults. Preliminary data suggests that the clearance of etanercept is reduced slightly in children ages 4 to 8 years. Population pharmacokinetic analyses predict that administration of 0.8 mg/kg of etanercept once weekly in children will result in C\(_{\text{max}}\) 11% higher, and C\(_{\text{min}}\) 20% lower at steady state as compared to administration of 0.4 mg/kg of etanercept twice weekly. The predicted pharmacokinetic differences between the regimens in JIA patients are of the same magnitude as the differences observed between twice weekly and weekly regimens in adult RA patients. Serum concentrations of etanercept in children with JIA aged 2 to 4 were similar to serum concentrations of etanercept in older children with JIA.

Concomitant methotrexate does not alter the pharmacokinetics of etanercept in adults. The pharmacokinetics of concomitant MTX in children with JIA ages 4 to 17 has not been evaluated.

*Gender:* Pharmacokinetic parameters were not different between men and women and did not vary with age in adult patients.
**Hepatic Insufficiency:** No formal pharmacokinetic studies have been conducted to examine the effect of hepatic impairment on etanercept disposition or potential interactions with methotrexate.

**Renal Insufficiency:** No formal pharmacokinetic studies have been conducted to examine the effect of renal impairment on etanercept disposition or potential interactions with methotrexate.

### 12 STORAGE, STABILITY AND DISPOSAL

**Erelzi Single-use Prefilled Syringe with Needle Guard and Erelzi Single-use Prefilled SensoReady® Pen**

Each Erelzi single-use prefilled syringe with Needle Guard (25 mg/0.5 ml and 50 mg/1.0 ml) and Erelzi single-use prefilled SensoReady® Pen (50 mg/1.0 mL) contain 50 mg/mL of etanercept in a single-dose syringe with a 27-gauge, ½-inch needle.

Erelzi should be stored refrigerated at 2°C to 8°C. **DO NOT FREEZE.** Do not use Erelzi beyond the expiration date stamped on the carton, Syringe or Pen product labels. **DO NOT SHAKE.** Keep the product in the original carton to protect from light until the time of use.

For convenience, storage of individual syringes or SensoReady® Pens at room temperature between 20°C to 25°C for a maximum single period of 28 days is permissible, with protection from light and sources of heat. Once a syringe or SensoReady® Pen has been stored at room temperature, it should not be placed back into the refrigerator. If not used within 28 days at room temperature, the syringe or SensoReady® Pens should be discarded. Do not store Erelzi in extreme heat or cold. **DO NOT FREEZE.** Keep in a safe place out of the reach of children.

### 13 SPECIAL HANDLING INSTRUCTIONS

**Information to Patients**

Erelzi is provided as a single-use prefilled syringe with a needle guard or a single-use prefilled SensoReady® Pen (autoinjector).

If a patient or caregiver is to administer Erelzi, he/she should be instructed in injection techniques to ensure the safe administration of Erelzi. The first injection should be performed under the supervision of a qualified health care professional. The patient’s or caregiver’s ability to inject subcutaneously should be assessed. Alcohol swabs and cotton balls or gauze are required for the injections and will need to be obtained separately. A puncture-resistant container for disposal of syringes, and prefilled pens should be used. Patients and caregivers should be instructed in the technique of proper syringe and needle disposal, and be cautioned against reuse of these items.
PART II: SCIENTIFIC INFORMATION

14 PHARMACEUTICAL INFORMATION

Drug Substance

Proper name: Etanercept

Chemical name: Not applicable. Etanercept is not a chemical. Etanercept is a Recombinant human Tumor Necrosis Factor Receptor: Fusion Protein (TNFR:Fc)

Molecular formula and molecular mass: Etanercept consists of 934 amino acids and has an apparent molecular weight of approximately 150 kilodaltons. The specific activity of etanercept is $1.7 \times 10^6$ U/mg.

Structural formula:

[Structural formula diagram]

Physicochemical properties: Erelzi is a clear and colorless to slightly yellowish, sterile, preservative free solution, and is formulated at pH 6.3 ± 0.2. There may be small white or almost transparent particles of protein in the solution. This is not unusual for proteinaceous solutions.

Product Characteristics

Erelzi (etanercept) is a dimeric fusion protein consisting of the extracellular ligand-binding portion of the human p75 tumor necrosis factor receptor (TNFR) linked to the Fc portion of human IgG1 (see illustration above). Etanercept is produced by recombinant DNA technology in a Chinese hamster ovary (CHO) mammalian cell expression system for use as a therapeutic inhibitor of tumor necrosis factor (TNF), a proinflammatory cytokine. Etanercept is composed entirely of human amino acid sequences. The Fc component of etanercept contains the $C_\text{H}2$ and $C_\text{H}3$ domains but not the $C_\text{H}1$ domain of IgG1.
15 COMPARATIVE CLINICAL TRIALS

15.1 Comparative Trial Design and Study Demographics

Clinical studies conducted to support similarity between Erelzi and the reference biologic drug included:

- Clinical pharmacokinetic (PK) study (GP15-104) in healthy male volunteers.
- Clinical efficacy and safety study (GP15-302) in patients with chronic plaque-type psoriasis.

A brief overview of the trial design and demographic characteristics of subjects enrolled in each trial is presented in Table 4.

Table 4. Summary of trial design and subject demographics

Enbrel/EU = EU-authorized Enbrel®; EP = Extension Period; N = number of total subjects/patients; PK = pharmacokinetic; s.c. = subcutaneous; TP = Treatment Period
Study GP15-104 was a randomized, double-blind, two-way cross-over study to compare the pharmacokinetics, safety and immunogenicity of Erelzi and Enbrel/EU following a single dose of 50 mg s.c. injection in healthy male subjects. The study evaluated 54 healthy male subjects.

Study GP15-302 was a randomized, double-blind, multicenter study which compared the efficacy, safety, and immunogenicity of Erelzi and the reference biologic drug in patients with chronic plaque-type psoriasis.

The study had an overall duration of 52 weeks and consisted of three periods:

- **Treatment Period 1 (up to Week 12):** At baseline 531 patients were randomized 1:1 into two groups to receive either Erelzi (264 patients) or Enbrel/EU (267 patients) at the recommended starting dose in psoriasis of 50 mg biweekly for 12 weeks.

- **Treatment Period 2 (Week 12 to Week 30):** Patients with at least a 50% reduction in PASI at Week 12 were re-randomized to maintain their initially randomized treatment or undergo pre-defined switches between Erelzi and Enbrel/EU at 6-week intervals. In Treatment Period 2 patients were treated with Erelzi or Enbrel/EU at a dose of 50 mg once weekly.

- **Extension Period (Week 30 to Week 52):** Patients received the treatment they had last received during Treatment Period 2, i.e. Erelzi or Enbrel/EU at a dose of 50 mg once weekly.

The eligible patient population consisted of adult male and female patients of at least 18 years of age with active, but clinically stable, chronic plaque-type psoriasis involving at least 10% of the body surface area, having a minimal Psoriasis Area and Severity Index (PASI) of 10 (indicating moderate-to-severe psoriasis). Patients had previously received at least one phototherapy or systemic therapy for psoriasis, or were candidates to receive such therapy in the opinion of the investigator. Randomization at baseline was stratified by body weight (< 90 kg; ≥ 90 kg) and prior systemic psoriasis therapy.

### 15.2 Comparative Study Results

#### 15.2.1 Comparative Bioavailability Studies

#### 15.2.1.1 Pharmacokinetics

**PK Study (GP15-104)**

Comparability criteria were met for the PK parameters Cmax and AUC0-tlast as the point estimate for the Erelzi and Enbrel/EU geometric mean ratios for Cmax and the 90 % CIs for the AUC0-tlast were within the acceptance margins of 0.80 to 1.25 (Table 5).

N = total number of patients within each treatment group; n = number of patients achieving PASI 75, PASI 50 and IGA (0, 1) response; respectively.

PASI = psoriasis area and severity index.

IGA = Investigator’s global assessment; patients were considered IGA responders if they achieved a score of 0 (“clear”) or 1 (“almost clear”) on the IGA rating scale.

*Primary endpoint: Equivalence in efficacy of Erelzi and Enbrel® based on PASI 75 response rate at week 12.

**An equivalence margin of 18% was used.

15.2.2.2 Safety

The types, frequency and severity of adverse events were comparable between the biosimilar and the reference biologic drug; please refer to Part I Adverse Reactions section.

15.2.2.3 Immunogenicity

Immunogenicity of Erelzi and Enbrel was assessed for the 531 psoriasis patients in Study GP15-302. Up to Week 12, 5 patients (1.9%) were confirmed positive for binding ADAs in the Enbrel group, while all patients in the Erelzi group were negative for binding ADAs. By the end of the study at week 52, one additional patient had tested positive for ADA binding while on Erelzi treatment. All positive ADA results had low titers, were transient and negative for neutralizing capacity.

16 COMPARATIVE NON-CLINICAL PHARMACOLOGY AND TOXICOLOGY

16.1 Comparative Non-Clinical Pharmacodynamics

**In vitro** Studies

Etanercept competitively inhibits binding of both TNF α and TNF β (lymphotoxin α [LT α]) to cell surface TNF receptors, rendering TNF biologically inactive. Therefore, Erelzi was compared to Enbrel® in several **in vitro** assays reflecting this mechanism of action (Table 7):

TNF-α: tumor necrosis factor alpha; TNF-β: tumor necrosis factor beta.

1) US and EU sourced Enbrel® was tested;

2) Potency was determined relative to an internal reference.
Several *in vitro* tests assessing integrity of the Fc domain were also conducted (binding to Fcγ receptors, FcRn and C1q; ADCC and CDC using genetically engineered cell lines). The range of CDC activity of Erelzi was slightly higher than for EU and US sourced Enbrel®. For ADCC, a lower activity was observed for Erelzi that correlates with differences in the relative amounts of fucosylated N-glycans as observed in the analytical characterization of Erelzi. These differences however, were not deemed important as CDC and ADCC activity are not considered to be relevant in the clinical mode of action of etanercept.

Overall, these results of the *in vitro* assays associated with the mechanism of action of etanercept and Fc related binding assays demonstrated comparability between Erelzi and Enbrel®.

**In vivo Studies**

Comparative efficacy of Erelzi and EU sourced Enbrel® was demonstrated in Tg197 transgenic mice that ectopically over-express human TNFα and develop chronic inflammatory polyarthritis. Tg197 exposed to either 10 mg/kg Erelzi or EU sourced Enbrel® by single or twice weekly intraperitoneal injection up to 4 weeks displayed significant inhibition of in-life arthritic pathology and underlying histopathology.

16.2 Comparative Toxicology

Erelzi is a biosimilar where the animal toxicology properties of etanercept have already been characterized for the reference biologic drug (See Part II, 18 Non-Clinical Toxicology – Reference Biologic Drug). Cynomolgus monkeys exposed to 15 mg/kg of Erelzi or EU sourced Enbrel® by single or repeated (once every 3 days) subcutaneous injections up to 4 weeks, displayed comparable toxicological profiles. No unexpected toxicities were identified for Erelzi.

**Adult Rheumatoid Arthritis**

Study demographics and trial design

The safety and efficacy of etanercept were assessed in four randomized, double blind, controlled studies and two long-term open-label studies. The results of all trials were expressed in percentage of patients with improvement in RA using American College of Rheumatology (ACR) response criteria.

Study I evaluated 234 patients with active RA who were ≥ 18 years old, had failed therapy with at least one but no more than four disease-modifying antirheumatic drugs (DMARDs: eg, hydroxychloroquine, oral or injectable gold, methotrexate (MTX), azathioprine, penicillamine, sulfasalazine), and had ≥ 12 tender joints, ≥ 10 swollen joints, and either ESR ≥ 28 mm/hr, CRP > 2.0 mg/dL, or morning stiffness for ≥ 45 minutes. Doses of 10 mg or 25 mg etanercept or placebo were administered SC twice a week for 6 consecutive months. Results from patients receiving 25 mg are presented in Table 9.

Study II evaluated 89 patients with similar inclusion criteria to Study I except that patients in Study II had additionally received MTX for at least 6 months, with a stable dose (12.5 to 25 mg/wk) for at least 4 weeks, and they had at least 6 tender or painful joints. Patients in Study II...
received a dose of 25 mg etanercept or placebo SC twice a week for 6 months in addition to their stable MTX dose.

Study III compared the efficacy of etanercept to MTX in patients with active RA. This study evaluated 632 patients who were ≥ 18 years old with early (< 3 years disease duration) active RA; had never received treatment with MTX; and had ≥ 12 tender joints, ≥10 swollen joints, and either ESR ≥ 28 mm/hr, CRP > 2.0 mg/dL, or morning stiffness for ≥ 45 minutes. Doses of 10 mg or 25 mg etanercept were administered SC twice a week for 12 consecutive months. The study was unblinded after all patients had completed at least 12 months (and a median of 17.3 months) of therapy. Results from patients receiving 25 mg are presented in Table 9. MTX tablets (escalated from 7.5 mg/week to a maximum of 20 mg/week over the first 8 weeks of the trial) or placebo tablets were given one a week on the same day as the injection of placebo or etanercept doses, respectively.

After the conclusion of Study III, patients could continue in a long-term extension study. This multicenter, open-label extension study followed 468 patients (mean age 50 years, 75% female at baseline) from Study III for up to 9.6 years. All patients received open-label 25 mg etanercept SC twice weekly, and were monitored to evaluate the effects of long-term etanercept administration on safety, health-related quality of life, and prevention of disability. Structural damage as measured by radiographic progression and clinical activity were evaluated at the 5 year time point.

Study IV evaluated 682 adult patients with active RA of 6 months to 20 years duration (mean 7 years) who had an inadequate response to at least one DMARD other than MTX. A minority of patients (43%) had previously received MTX for a mean of two years prior to the trial at a mean dose of 12.9 mg. Patients were excluded from this study if MTX had been discontinued for lack of efficacy or for safety considerations.

Patients were randomized to MTX alone (7.5 to 20 mg weekly, median dose 20 mg), etanercept alone (25 mg twice weekly), or the combination of etanercept and MTX initiated concurrently (at the same doses as above). The study evaluated ACR response, Disease Activity Score (DAS), Sharp radiographic score and safety.

Another long-term extension study followed patients with DMARD-refractory RA (defined as less-than-optimal response to ≥ 1 previous DMARD) who had been enrolled from 8 previous etanercept studies. This multicenter, long-term extension study evaluated the effectiveness and safety of more than 10 years of etanercept treatment in 581 patients (mean age 50 years, 80% female at baseline). Drug was administered as 50 mg weekly subcutaneous dose of etanercept as two 25 mg injections on the same day or 3 to 4 days apart. These patients were followed for up to 11.3 years to evaluate the long-term safety of etanercept and improvement in physical function (5-year evaluation)/disability and quality of life.

Study results
The percent of etanercept-treated patients achieving ACR 20, 50, 70 responses was consistent across all 4 trials. The results of Studies I, II and III are summarized in Table 9. The results of Study IV are summarized in Table 11.

c p < 0.05, etanercept vs. MTX

* Study III was conducted in patients who were MTX naive.

The time course of ACR 20 response rates for patients receiving placebo or 25 mg etanercept in Studies I and II is summarized in Figure 1. The time course of responses to etanercept in Study III was similar.
Among patients receiving etanercept, the clinical responses generally appeared within 1 to 2 weeks after initiation of therapy and nearly always occurred by 3 months. A dose response was seen in Studies I and III: 25 mg etanercept was more effective than 10 mg (10 mg was not evaluated in Study II). Etanercept was significantly better than placebo in all components of the ACR criteria as well as other measures of RA disease activity not included in the ACR response criteria, such as morning stiffness. Only a small number of patients were treated in the controlled clinical trial (Study II) with the combination of etanercept and MTX (N = 59 for Etanercept/MTX combination; N = 30 for MTX alone) and for a relatively short period of time (6 months).

In Study III, ACR response rates and improvement in all the individual ACR response criteria were maintained through 24 months of etanercept therapy. Over the 2-year study, 23% of etanercept patients achieved a major clinical response, defined as maintenance of an ACR 70 response over a 6-month period.

In the open label extension for Study III, ACR 20, 50 and 70 responses were observed through 5 and 10 years. Of 468 patients, 297 patients continued on etanercept treatment through 5 years.

Of those, 61%, 49% and 30% had ACR 20, ACR 50, and ACR 70 responses, respectively, at 5 years. Of these 297 patients, 168 patients continued on etanercept treatment through 9.6 years, of those, 66%, 46%, and 30% had ACR 20, ACR 50 and ACR 70 responses, respectively, at 9 years.

The results of the components of the ACR response criteria for Study I are shown in Table 10. Similar results were observed for etanercept-treated patients in Studies II and III.

c Scale 0-68.
d Visual analog scale; 0 = best, 10 = worst.
e Health assessment questionnaire; 0 = best, 3 = worst; includes eight categories: dressing and grooming, arising, eating, walking, hygiene, reach, grip, and activities.
f p < 0.01, etanercept vs. placebo, based on mean percent change from baseline.

An additional randomized, controlled, double-blind trial evaluated 180 patients with similar criteria to Study I. Doses of 0.25 mg/m², 2 mg/m², and 16 mg/m² etanercept were administered SC twice a week for 3 consecutive months. A dose-dependent increase in the proportion of patients achieving an ACR 20 response was seen, with 75% of patients responding in the highest dose group (16 mg/m² etanercept).

After discontinuation of etanercept, symptoms of arthritis generally returned within a month. Reintroduction of treatment with etanercept after discontinuations of up to 18 months resulted in the same magnitudes of response as patients who received etanercept without interruption of therapy based on results of open-label studies.

Continued durable responses were also seen for approximately 10 years in a second open-label extension trial with etanercept treatment. Of 581 patients, 365 patients continued on etanercept treatment through 5 years. Of those, 73%, 49%, and 24% had ACR 20, ACR 50 and ACR 70 responses, respectively, at 5 years. Of the 365 patients, 225 patients continued on etanercept treatment through 10 years. Of those, 71%, 52%, and 27% had ACR 20, ACR 50 and ACR 70 responses, respectively, at 10 years. Fifty seven to 83% of patients who initially received concomitant MTX or corticosteroids were able to reduce their doses or discontinue these concomitant therapies while maintaining their clinical response.

In Study IV, patients initiating the combination of etanercept and MTX had significantly higher ACR 20, ACR 50, and ACR 70 responses and improvement for DAS scores at both 6 and 12 months than patients in either of the single therapy groups (Table 11). Twenty-four percent of patients treated with etanercept and MTX concurrently achieved a major clinical response within 12 months.

The percentage of patients who achieved low disease activity (defined as DAS < 2.4) at 12 months was 35%, 39%, and 61% for patients in the MTX alone group, etanercept alone group, and the etanercept/MTX combination group, respectively. Remission (defined as DAS < 1.6)
was experienced by 14%, 18%, and 37% of patients administered MTX alone, etanercept alone, and etanercept/MTX combination therapy, respectively.

Physical Function Response

In Studies I, II, and III, physical function and disability were assessed using the Health Assessment Questionnaire (HAQ). Additionally, in Study III, patients were administered the SF-36 Health Survey. In Studies I and II, patients treated with 25 mg etanercept twice weekly showed greater improvement from baseline in the HAQ score beginning in month 1 through month 6 in comparison to placebo (p < 0.001) for the HAQ disability index (HAQ-DI) (where 0 = none and 3 = severe). In Study I, the mean improvement in the HAQ score from baseline to month 6 was 0.6 (from 1.6 to 1.0) for the 25 mg etanercept group and 0 (from 1.7 to 1.7) for the placebo group. In Study II, the mean improvement from baseline to month 6 was 0.7 (from 1.5 to 0.7) for 25 mg etanercept twice weekly. All subdomains of the HAQ in Studies I and III were improved in patients treated with etanercept.

In Study III, patients treated with 25 mg etanercept twice weekly showed greater improvement from baseline in SF-36 physical component summary score compared to etanercept 10 mg twice weekly and no worsening in the SF-36 mental component summary score.

In open-label etanercept studies, improvements in physical function and disability measures (HAQ-DI) have been maintained for over 10 years. In the first study in patients with DMARD-
refractory RA for a mean of 13 years, the mean baseline HAQ-DI was 1.5 (measured prior to/on the day of the first dose of etanercept treatment in the etanercept-initiating study). At Year 10, the mean HAQ-DI was 1.0, a mean percent improvement of 21. In a second study in patients who had been diagnosed with RA for a mean of 3 years, the mean baseline HAQ-DI was 1.3. At Year 9, the mean HAQ-DI was 0.7, a mean percent improvement of 31.

In Study IV, mean HAQ scores improved from baseline levels of 1.7, 1.7, and 1.8 to 1.1, 1.0, and 0.8 at 12 months in the MTX, etanercept, and etanercept /MTX combination treatment groups, respectively (Combination versus both MTX and etanercept, p < 0.01). Twenty-nine percent of patients in the MTX alone treatment group had an improvement of HAQ of at least one unit versus 40% and 51% in the etanercept alone and the etanercept /MTX combination treatment groups, respectively. Further, 24% of patients in the combination treatment group who registered some disability in HAQ at baseline had improved to a HAQ of 0 (no disability) by month 12.

Radiographic Response

In Study III, structural joint damage was assessed radiographically and expressed as change in total Sharp score (TSS) and its components, the erosion score and joint space narrowing (JSN) score. Radiographs of hands/wrists and forefeet were obtained at baseline, 6 months, 12 months, and 24 months and scored by readers who were unaware of treatment group. The results are shown in Table 12. A significant difference for change in erosion score was observed at 6 months and maintained at 12 months.

*95% confidence intervals for the differences in change scores between MTX and Etanercept

Patients continued on the therapy to which they were randomized for the second year of Study III. Seventy-two percent of patients had x-rays obtained at 24 months. Compared to the MTX group, greater inhibition of progression in TSS and erosion score was seen in the 25 mg etanercept group, and in addition, less progression was noted in the JSN score. These differences did not reach statistical significance.

In the open-label extension (fifth year of Study III), patients treated with 25 mg etanercept had continued inhibition of structural damage. Patients originally treated with MTX had further reduction in radiographic progression once they began treatment with etanercept.
In Study IV, significantly less radiographic progression (TSS) was observed with etanercept in combination with MTX compared with etanercept alone or MTX alone at month 12 (Figure 2). In the MTX treatment group 57% of patients experienced no radiographic progression (TSS change ≤ 0.5) at 12 months compared to 68% and 80% in the etanercept alone and the etanercept/MTX combination treatment groups, respectively. Significant regression in TSS (-0.54) was observed in the etanercept/MTX combination treatment group at 12 months [95% CI, (-1.00 to –0.07)], indicating the inhibition of structural damage.

ES = Erosion score

**Results in Geriatric Patients**

A total of 480 geriatric (age ≥ 65 years) RA patients have been studied in clinical trials. Their clinical responses were comparable to responses seen in RA patients < 65 years of age.

**Once Weekly Dosing**
The safety and efficacy of 50 mg etanercept (two 25 mg SC injections) administered once weekly were evaluated in a double-blind, placebo-controlled study of 420 patients with Active RA. In this study, 53 patients received placebo, 214 patients received 50 mg etanercept once weekly, and 153 patients received 25 mg etanercept twice weekly (72 to 96 hours apart). The safety and efficacy profiles of the two etanercept treatment groups were similar.
Other Studies
An open-label, single-arm study was conducted to assess the safety and immunogenicity of etanercept manufactured by a modified process, administered weekly for up to 24 weeks in 220 RA patients who were etanercept-naïve and not receiving methotrexate therapy. The immunogenicity data are comparable to those observed in other studies with etanercept. Positive binding antibodies were detected in 4.5% of patients at week 12 and 0.5% at week 24. In this study, as in previous studies, no patient tested positive for neutralizing antibodies. Overall, the safety profile (both adverse events and immunogenicity) was comparable to the etanercept manufactured using the previous process (see PART I/ADVERSE REACTIONS/Clinical Trial Adverse Reactions).

Polyarticular Juvenile Idiopathic Arthritis (JIA)

Study demographics and trial design

The safety and efficacy of etanercept were assessed in a two-part study in 69 children with polyarticular JIA who had a variety of JIA onset types. Patients aged 4 to 17 years with moderately to severely active polyarticular JIA refractory to or intolerant of methotrexate were enrolled; patients remained on a stable dose of a single nonsteroidal anti-inflammatory drug and/or prednisone (≤ 0.2 mg/kg/day or 10 mg maximum). In part 1, all patients received 0.4 mg/kg (maximum 25 mg per dose) etanercept SC twice weekly. In part 2, patients with a clinical response at day 90 were randomized to remain on etanercept or receive placebo for four months and assessed for disease flare. Responses were measured using the JIA Definition of Improvement (DOI), defined as a ≥ 30% improvement in at least three of six and ≥ 30% worsening in no more than one of six JIA core set criteria, including active joint count, limitation of motion, physician and patient/parent global assessments, functional assessment, and ESR. Disease flare was defined as a ≥ 30% worsening in three of the six JIA core set criteria and ≥ 30% improvement in not more than one of the six JIA core set criteria and a minimum of two active joints.

Study Results

In part 1 of the study, 51 of 69 (74%) patients demonstrated a clinical response and entered part 2. In part 2, 7 of 25 (28%) patients remaining on etanercept experienced a disease flare compared to 21 of 26 (81%) patients receiving placebo (p = 0.0030). From the start of part 2, the median time to flare was ≥ 116 days for patients who received etanercept and 28 days for patients who received placebo. Each component of the JIA core set criteria worsened in the arm that received placebo and remained stable or improved in the arm that continued on etanercept. The data suggested the possibility of a higher flare rate among those patients with a higher baseline ESR. Of patients who demonstrated a clinical response at 90 days and entered part 2 of the study, some of the patients remaining on etanercept continued to improve from month 3 through month 7, while those who received placebo did not improve.

The majority of JIA patients who developed a disease flare in part 2 and were reintroduced to etanercept treatment up to 4 months after discontinuation re-responded to etanercept therapy, in open-label studies. Durable response has been observed for over 4 years in JIA patients.

Studies have not been done in patients with polyarticular JIA to assess the effects of continued etanercept therapy in patients who do not respond within 3 months of initiating etanercept therapy, or to assess the combination of etanercept with methotrexate.

Ankylosing Spondylitis

Study demographics and trial design

The safety and efficacy of etanercept were assessed in a randomized, double-blind, placebo-controlled study in 277 patients with ankylosing spondylitis. Patients were between 18 and 70 years of age and had active ankylosing spondylitis as defined by the modified New York Criteria for Ankylosing Spondylitis. Patients taking hydroxychloroquine, sulfasalazine, or methotrexate (stable for 4 weeks prior to study start) could continue these drugs at stable doses for the duration of the study. Doses of 25 mg etanercept or placebo were administered SC twice a week for 6 months. Patients who participated in this double-blind study were eligible to enter into an open-label follow-up study where all patients received 25 mg SC twice weekly or 50 mg once weekly for up to 42 months.

Study Results

The primary measure of efficacy was a 20% improvement in the Assessment in Ankylosing Spondylitis (ASAS) response criteria. Compared to placebo, treatment with etanercept resulted in significant improvements in the ASAS and other measures of disease activity in patients with ankylosing spondylitis (Figure 3 and Table 15).

At 12 weeks, the ASAS 20/50/70 responses were achieved by 60%, 45%, and 29%, respectively, of patients receiving etanercept, compared to 27%, 13%, and 7%, respectively, of patients receiving placebo (p ≤ 0.0001, etanercept vs. placebo). Similar responses were seen at week 24.

\( ^a \) p < 0.0015 for all comparisons between Etanercept and placebo at 6 months. P-values for continuous endpoints were based on percent change from baseline.

b. Measured on a VAS scale with 0 = “none” and 100 = “severe.”

c. Average of total nocturnal and back pain scores, measured on a VAS scale with 0 = “no pain” and 100 = “most severe pain.”

d. Bath Ankylosing Spondylitis Functional Index (BASFI), average of 10 questions.

e. Inflammation represented by the average of the last 2 questions on the 6-question Bath Ankylosing Spondylitis Disease Activity Index (BASDAI).

f. C-reactive protein (CRP) normal range: 0 – 1.0 mg/dL.

g. Erythrocyte sedimentation rate (ESR) normal range: 1–17 mm/hr for men; 1–25 mm/hr for women.

Among patients with ankylosing spondylitis who received etanercept, the clinical responses were apparent as early as 2 weeks, reach maximum within the first 2 months on study, and were maintained through 6 months of therapy. Responses were similar in patients who were not receiving concomitant therapies at baseline. The results of this study were similar to those seen in an earlier single-center, randomized, placebo-controlled study of 40 patients with ankylosing spondylitis and a multi-center, randomized, placebo-controlled study of 84 patients with ankylosing spondylitis.

Regardless of treatment group in the initial double-blind study, ASAS 20/50/70, BASDAI, and BASFI responses were maintained or improved in patients treated with etanercept during a 42-month open-label extension study. Although patient-reported outcomes were not collected during the controlled period of the study, patients who had received placebo in controlled period showed rapid improvement in patient-reported outcomes (SF-36 and EQ-5D) with etanercept treatment by week 12 of the open-label study. Improvement in patient-reported outcomes was sustained over 4 years in both the previous placebo and etanercept groups.
The preclinical toxicologic profile of TNFR:Fc was evaluated in monkeys, rats, mice and rabbits. Multidose toxicity studies were conducted in monkeys following repeat administration by intravenous, subcutaneous or oronasal inhalation routes. The incidence and time course of neutralizing antibody formation were characterized in toxicity and reproductive toxicity studies, as well as in special toxicology studies in mice, rats and rabbits.

TNFR:Fc was well tolerated in all species used in preclinical toxicology studies at doses representing large multiples (up to 30x in monkeys, and up to 100x in rats and rabbits) of the maximum human therapeutic dose of 0.5 mg/kg. These doses resulted in systemic exposure levels (based on AUC) that were up to about 30, 45 and 74 times higher than human exposure at the maximum therapeutic dose, in monkeys, rats, and rabbits, respectively.

**Multidose Toxicity**

No adverse effects were observed in monkeys administered twice-weekly subcutaneous injections of TNFR:Fc at 1, 5 and 15 mg/kg for 28 days. The only potentially treatment-related change was increased adrenal gland weights in female monkeys for the 5 and 15 mg/kg doses (34% and 54% increase in weight, respectively, compared to control). This finding was not considered of toxicologic importance, as adrenal weights for females at 5 and 15 mg/kg were within the facility's historical control range for untreated females. In addition, no macroscopic or microscopic pathologic changes occurred in adrenals, there were no clinical pathologic changes indicative of adrenal function effects, and no changes in adrenal weights were present in males at any dose. Adrenal weights for females receiving a dose of 1 mg/kg were comparable to vehicle control values. $C_{\text{max}}$ and AUC increased with increasing dose on Days 1 and 22. These increases were dose proportional on Day 1. AUC0-00 at 15 mg/kg on Day 22 was approximately 30 times the anticipated human exposure. Systemic exposure in Cynomolgus monkeys at 1 and 5 mg/kg was reduced at Day 22 compared to Day 1 values. The decrease in $C_{\text{max}}$ and AUC at 1 and 5 mg/kg is attributed to the formation of polyclonal anti-TNFR:Fc antibodies, which interfere with the quantitative ELISA method used for measurement of TNFR:Fc concentrations and increased antibody-mediated clearance. It is possible that at the higher dose of 15 mg/kg, the antibody response may be saturated or suppressed by the higher levels of TNFR:Fc.

No adverse effects have been reported through Week 14 of an ongoing 26 week study in which monkeys are administered TNFR:Fc by twice-weekly subcutaneous injection at 1, 5 and 15 mg/kg.

No treatment-related effects were observed in monkeys after two weeks of twice-weekly subcutaneous injections of either of two lots of TNFR:Fc produced at two different manufacturing facilities and production scales at 15 mg/kg. There were no toxicokinetic differences and no neutralizing antibodies were detected in monkeys following administration of either lot.

No treatment-related effects occurred in monkeys administered TNFR:Fc at 0.2 or 2.0 mg/kg subcutaneously daily for 20 days. No delayed toxicity was observed in monkeys retained for 14 days following cessation of treatment.

No treatment-related effects occurred in monkeys administered intravenous TNFR:Fc at 1.5 or 15 mg/kg as a single dose, or daily for 3 consecutive days. No delayed toxicity occurred in monkeys retained for 18 days following cessation of treatment.
Injection site reactions were minimal with repeated administration of TNFR:Fc by intravenous or subcutaneous injection.

The only treatment-related effects in monkeys administered 0.15 and 0.70 mg/kg/day TNFR:Fc via daily inhalation for 28 days were specific to this route of administration. Increased lung weight and microscopic perivascular cell infiltration and intra-alveolar histiocytosis were present in lungs at both dose levels. Minor increases in the number of granulocytic cells and myeloid erythroid (M:E) ratio were observed in bone marrow in one female monkey each in both TNFR:Fc-treated groups compared to the control group.

**Special Toxicity**
Neutralizing antibodies were detected in mice, rats, rabbits and Cynomolgus monkeys after multiple doses of TNFR:Fc administered by intravenous, subcutaneous or oronasal routes. In general, the incidence of both anti-TNFR:Fc and neutralizing antibodies increased with time. Anti-TNFR:Fc antibodies were detected in monkeys after 15 days of twice weekly subcutaneous administration, and were present in almost all animals by 3 to 4 weeks. In monkeys receiving daily subcutaneous injections of TNFR:Fc for 20 days, anti-TNFR:Fc antibodies continued to circulate for at least 14 days after drug administration was discontinued.

Neutralizing antibodies were detected as early as 1 week after the initiation of twice weekly subcutaneous administration of 1 mg/kg TNFR:Fc in mice and rats, and by 10 days in rabbits. After 4 weeks of twice weekly subcutaneous TNFR:Fc, neutralizing antibodies were detected in almost all mice, rats or rabbits administered 1 or 25 mg/kg TNFR:Fc. No neutralizing antibodies were detected in reproductive studies in rats following TNFR:Fc administration to pregnant rats by daily injections at 5 to 50 mg/kg for 12 days or at 3 to 30 mg/kg for up to 15 days. Neutralizing antibodies were detected in pregnant rabbits after 15 days of subcutaneous dosing at 5, 15 and 50 mg/kg. The incidence of neutralizing antibodies was lower and the time to appearance longer in monkeys than in other species.

Following twice weekly subcutaneous TNFR:Fc administration to monkeys, neutralizing antibodies were detected in 1 of 6 monkeys treated with 1 mg/kg TNFR:Fc on Day 26. No neutralizing antibodies were detectable by Day 26 in monkeys administered TNFR:Fc subcutaneously, twice weekly, at 5 or 15 mg/kg. These data support the selection of the monkey as the species of choice in multiple-dose toxicity studies.

The incidence of anti-TNFR:Fc antibodies and neutralizing antibodies appeared to be lower at higher doses of TNFR:Fc. One explanation for this observation is that the antibody ELISA can only detect free anti-TNFR:Fc antibodies ie, those not bound to TNFR:Fc in the serum sample. Only a low antibody incidence will be detected even in the presence of high levels of circulating anti-TNFR:Fc antibodies, if those antibodies are bound to TNFR:Fc. An alternate explanation is that high levels of TNFR:Fc may saturate or suppress the antibody response.

The detection of neutralizing antibodies is also compromised in the presence of circulating antibody-TNFR:Fc complexes. A serum concentration of 100 ng/mL TNFR:Fc is sufficient to negate antibody detection by the neutralizing antibody assays. Neutralizing antibodies were detected in monkeys administered TNFR:Fc via inhalation. The lower TNFR:Fc serum concentrations (< 60 ng/mL) observed in this study, compared to other monkey studies, would not interfere with the detection of neutralizing antibodies.
Reproductive Toxicity
There were no adverse effects of TNFR:Fc on pregnant rats or rabbits or their offspring following daily subcutaneous administration during the period of organogenesis at doses up to 100 times the intended clinical dose. These doses resulted in systemic exposures up to approximately 45 to 74 fold higher in rats and rabbits than human exposure at the maximum therapeutic dose, based on AUC. The rat or rabbit AUC$_{0-24}$ values were multiplied by 3 to compare daily dosing in rats or rabbits to dosing every 3 days in humans in determining these exposure ratios (rat or rabbit AUC/human AUC).

The pharmacokinetic profile of TNFR:Fc in pregnant animals was similar to that observed in non-pregnant rats and monkeys.

Neutralizing antibodies were detected in the rabbits, but not in the rat, following daily subcutaneous administration of TNFR:Fc during the period of organogenesis.

Mutagenicity
TNFR:Fc is not considered to represent a genotoxic hazard to humans based on the results of bacterial mutagenicity, mouse lymphoma cell mutagenicity, human chromosomal aberrations, and mouse micronucleus assays.
19  SUPPORTING PRODUCT MONOGRAPHS

1. P"Enbrel®, Product Monograph, Control number: 179298; Dated: October 19, 2015, Amgen Canada Inc
READ THIS FOR SAFE AND EFFECTIVE USE OF YOUR MEDICINE

PATIENT MEDICATION INFORMATION

ERELZI (pronounced <eh-rel-zee>)
(etanercept)
Single-use Prefilled Syringe with Needle Guard

Read this carefully before you start taking Erelzi and each time you get a refill. This leaflet is a summary and will not tell you everything about this drug. Talk to your healthcare professional about your medical condition and treatment and ask if there is any new information about Erelzi.

Erelzi is a biosimilar biologic drug (biosimilar) to the reference biologic drug Enbrel®. A biosimilar is authorized based on its similarity to a reference biologic drug that was already authorized for sale.

Serious Warnings and Precautions

- **Serious infections.** There have been cases where patients taking etanercept or other TNF-blocking agents have developed serious infections, including tuberculosis (TB) and infections caused by bacteria, viruses or fungi that have spread throughout their body. Some patients have died from these infections. In very rare cases, hepatitis B recurred in patients with previous hepatitis. If you tend to get infections easily or if you develop an infection while taking etanercept, you should tell your doctor right away.

- **Malignancies.** There have been cases, sometimes fatal, of unusual cancers in children and teenage patients who started using TNF-blocking agents, including etanercept, at less than 18 years of age.

What is Erelzi used for:
Erelzi is a medicine for treating people with moderate to severe forms of rheumatoid arthritis (RA) or juvenile idiopathic arthritis (JIA). Erelzi is also for treating adults with a type of arthritis called ankylosing spondylitis (AS). RA, JIA, and AS are inflammatory diseases that affect the joints in your body.

How does Erelzi work:
Erelzi is a type of protein called a tumour necrosis factor (TNF) blocker that blocks the action of a substance your body makes called TNF-alpha. TNF-alpha is made by your body’s immune system. People with immune diseases like RA, JIA, as well as patients with AS, have too much TNF-alpha in their bodies, which can cause inflammation and lead to painful, swollen joints. Erelzi can reduce the amount of TNF in the body to normal levels, helping to treat joint damage. In patients with inflammatory arthritis, Erelzi may be effective in reducing signs and symptoms of inflammatory arthritis (such as pain, morning stiffness and fatigue), may help improve your ability to do simple daily activities (such as dressing, walking and climbing stairs), and may help prevent damage to your bones and joints.
When can I expect to see results from taking Erelzi?
Improvement may be seen as early as 1 week after starting etanercept in adults and within 2 weeks in children. In clinical trials, full effect was usually seen by 3 months in both adults and children and was sustained with continued treatment.

What are the ingredients in Erelzi?
Medicinal ingredient: etanercept.
Non-medicinal ingredients: citric acid, L-lysine hydrochloride, sodium chloride, sodium citrate and sucrose.

Erelzi comes in the following dosage forms:
Erelzi Single-use Prefilled Syringes with Needle Guard are available in 25 mg (0.5 mL of a 50 mg/mL solution of etanercept) and 50 mg (1.0 mL of a 50 mg/mL solution of etanercept).
Erelzi Single-use Prefilled SensoReady® Pens are available in 50 mg (1.0 mL of a 50 mg/mL solution of etanercept).

Do not use Erelzi if:
- You should not take Erelzi if you have ever had an allergic reaction to etanercept or any of the ingredients in Erelzi.
- You should not take Erelzi if you have an infection that has spread through your body (sepsis).

To help avoid side effects and ensure proper use, talk to your healthcare professional before you take Erelzi. Talk about any health conditions or problems you may have, including if you:
- have an infection. This could put you at risk for serious side effects from etanercept.
- have symptoms of an infection such as fever, sweats or chills, cough or flu-like symptoms, shortness of breath, blood in your phlegm, weight loss, muscle aches, warm, red, or painful areas on your skin, sores on your body, diarrhea or stomach pain, burning when you urinate or urinate more often than normal, and feel very tired.
- have a history of infections that keep coming back or other conditions — like diabetes, HIV, or a weak immune system — that might increase your risk of infections.
- have tuberculosis (TB), or have been in close contact with someone who has or has had TB. You will need to be evaluated for TB. Your doctor should test you for TB before starting etanercept.
- were born in, lived in, or traveled to countries where there is a risk for getting TB. Ask your doctor if you are not sure.
- live in, have lived in or have traveled to, areas where there is a greater risk for certain kinds of fungal infections (histoplasmosis, coccidioidomycosis, blastomycosis). These infections may develop or become more severe if you take etanercept. If you don’t know if you have lived in an area where these infections are common, ask your doctor.
- have or have had hepatitis B.
- have or have had persistent numbness, tingling and muscle weakness or a disease such as multiple sclerosis, Guillain-Barré or a Guillain-Barré-like syndrome, which causes inflammation of the nervous system, either in the brain and spinal cord or nerves going to your hands and feet.
- have been newly diagnosed or are being treated for congestive heart failure.
- are scheduled to have major surgery.
• have recently received or are scheduled to receive a vaccine. All vaccines should be brought up-to-date before starting etanercept. Patients taking etanercept should not receive live vaccines.
• use the medication Kineret® (anakinra), Ocrevus® (abatacept) or cyclophosphamide (see INTERACTIONS WITH THIS MEDICATION below).
• have been around someone with varicella zoster (chicken pox, shingles)

Know the medicines you take. Keep a list of them to show your doctor and pharmacist each time you get a new medicine.

Your doctor should monitor you closely for signs and symptoms of TB during treatment with etanercept even if you have tested negative for TB. If you develop any of the symptoms of TB (a dry cough that doesn’t go away, weight loss, fever, night sweats) call your doctor.

If you are not sure or have any questions about any of this information, ask your doctor.

Other warnings you should know about:

All medicines have side effects. Medicines, like Erelzi, that affect your immune system can cause serious side effects. The possible serious side effects include:

• **Nervous system diseases.** There have been rare cases of disorders that affect the nervous system of people taking etanercept or other TNF blockers, such as multiple sclerosis, seizures or inflammation of the nerves of the eyes. Signs that you could be experiencing a problem affecting your nervous system include: numbness or tingling throughout your body, problems with your vision, weakness in your arms and/or legs, and dizziness.

• **Blood problems.** In some patients the body may fail to produce enough of the blood cells that can help your body fight infections or help you to stop bleeding. This can lead to death. If you develop a fever that doesn’t go away, bruise or bleed very easily or look very pale or feel faint, call your doctor right away. Your doctor may decide to stop treatment. Some people have also had symptoms that resemble lupus (rash on your face and arms that gets worse in the sun) that may go away when you stop taking etanercept.

• **Heart problems.** You should also tell your doctor if you have ever been treated for heart failure. If you have, your doctor may choose not to start you on etanercept, or may want to monitor you more closely. Symptoms include shortness of breath or swelling of your ankles and feet.

• **Allergic reactions.** Some patients have had allergic reactions to etanercept. If you develop a severe rash, swollen face or difficulty breathing while taking etanercept, call your doctor right away.

• **Malignancies.** Patients with inflammatory diseases including RA or AS, particularly those with highly active disease, may be at higher risk for lymphoma (a type of cancer). For children and adults taking TNF-blocker medicines including etanercept, the chances of getting lymphoma or other cancers may increase. Whether treatment with etanercept might influence the development and course of malignancies in adults is unknown.

• **Liver problems** (autoimmune hepatitis). Liver problems can happen in people who use TNF blocker medicines, including etanercept. These problems can lead to liver failure.
and death. Call your doctor right away if you have any of these symptoms: feel very
tired, skin or eyes look yellow, poor appetite or vomiting, pain on the right side of your
stomach (abdomen). These symptoms may occur several months after starting and even
after etanercept has been stopped.

- **Serious infections.** Etanercept can lower the ability of your immune system to fight
infections. So, taking etanercept can make you more prone to getting infections or make
any infection that you may have worse. Some people have serious infections while
taking etanercept including infections that spread through the body such as tuberculosis
(TB), legionellosis (usually a bacterial pneumonia), and listeriosis (usually from
contaminated food). Other infections caused by viruses, fungi, bacteria or parasites may
occur. Some people have died from these infections.

**What are the common side effects?**
In studies comparing etanercept to placebo (inactive injection), side effects that occurred more
frequently in patients treated with etanercept were:
- Reactions where the injection was given. These reactions are usually mild and include
  redness, swelling, itching, or bruising. These usually go away within 3 to 5 days. If you
  have pain, redness or swelling around the injection site that doesn’t go away or gets
  worse, call your doctor.
- Upper respiratory infections (sinus infections)
- Headaches

**Can I take Erelzi if I am pregnant or breastfeeding?**
Etanercept has not been studied in pregnant women or nursing mothers, therefore its effects on
pregnant women or nursing babies are not known.

You should tell your doctor if you are pregnant, become pregnant or are thinking about
becoming pregnant. If you took etanercept during pregnancy, talk to your doctor prior to
administration of live vaccines to your infant.

Etanercept can pass into breast milk. You and your doctor should decide if you will take
etanercept or breastfeed. You should not do both.

If you are not sure or have any questions about any of this information, ask your doctor.

**Tell your healthcare professional about all the medicines you take, including any drugs,
vitamins, minerals, natural supplements or alternative medicines.**

It is important that you tell your doctor about any other medicines (for example, high blood
pressure medicine) you are taking for other conditions before you start taking etanercept. You
should also tell your doctor about any over-the-counter drugs, herbal medicines and vitamin and
mineral supplements you are taking.

If you have diabetes and are taking medication to control your diabetes, your doctor may decide
you need less anti-diabetic medicine while taking etanercept.
Can I take Erelzi if I am taking other medicines for my RA, JIA, AS or other conditions?

In adults, Erelzi can be used in combination with methotrexate. However, little is known of the interaction of etanercept with methotrexate and other drugs in children with juvenile idiopathic arthritis.

The following may interact with Erelzi:

- Taking etanercept with Kineret® (anakinra) is not recommended because this may increase your risk of getting a serious infection.
- Taking etanercept with Orencia® (abatacept) is not recommended because this may increase your risk for serious side effects.
- Taking etanercept with cyclophosphamide (used to treat cancer or immune diseases) is not recommended. You may have a higher chance for getting certain cancers when taking Erelzi with cyclophosphamide.

How to take Erelzi:

Usual dose:
Erelzi is given as an injection under the skin.

You may continue to use other medicines that help treat your condition while taking Erelzi, such as non-steroidal anti-inflammatory drugs (NSAIDs) and prescription steroids, as recommended by your doctor.

If you have RA or AS, the recommended dose of Erelzi for adults is 50 mg per week given as one injection using a 50 mg single-use prefilled syringe or two injections using the 25 mg single-use prefilled syringe. Your doctor will tell you whether the two injections with the 25 mg single-use prefilled syringe should be given on the same day once a week or on two different days (3 or 4 days apart) in the same week.

The recommended dose of Erelzi for children with juvenile idiopathic arthritis is based on the child’s body weight. Your child’s doctor will tell you the correct amount of Erelzi your child should take and will prescribe an appropriate strength of etanercept. Erelzi is available for treatment of children and adolescents weighing 63 kg (138 pounds) or more.

Make sure you have been shown how to inject Erelzi before you do it yourself. Someone you know can also help you with your injection. Remember to take this medicine just as your doctor has told you and do not miss any doses.
Instructions for Use of the Erelzi pre-filled syringe

Read ALL the way through these instructions before injecting. It is important not to try to inject yourself until you have been trained by your doctor, nurse or pharmacist. The box contains Erelzi pre-filled syringe(s) individually sealed in a plastic blister.

**Needle Guard ACTIVATED – DO NOT USE**
In this configuration the needle guard is ACTIVATED – DO NOT USE the pre-filled syringe

**Device READY TO BE USED**
In this configuration the needle guard is NOT ACTIVATED and the pre-filled syringe is ready for use

Your Erelzi pre-filled syringe with needle guard and add-on finger flange

After the medicine has been injected, the needle guard will be activated to cover the needle. This is intended to aid in the protection of healthcare professionals, patients who self-inject doctor-prescribed medicines and individuals who assist self-injecting patients from accidental needle stick injuries.

**What you additionally need for your injection:**

- Alcohol swab
- Cotton ball or gauze
- Sharps disposal container

**Important Safety Information:**

**Caution: Keep the syringe out of the sight and reach of children.**
1. Do not open the outer box until you are ready to use this medicine.
2. Do not use this medicine if the seal of the blister is broken, as it may not be safe for you to use.
3. Do not shake the syringe.
4. Never leave the syringe lying around where others might tamper with it.
5. The pre-filled syringe has a needle guard that will be activated to cover the needle after the injection is finished. The needle guard will help to prevent needle stick injuries to anyone who handles the pre-filled syringe.
Be careful not to touch the needle guard wings before use. By touching them, the needle guard may be activated too early.

6. Do not remove the needle cap until just before you give the injection.

7. The syringe cannot be re-used. Dispose of the used syringe immediately after use in a sharps container.

Storage of the Erelzi pre-filled syringe

1. Store this medicine in its outer box to protect from light. Store in the refrigerator between 2°C to 8°C. DO NOT FREEZE.
2. Remember to take the blister out of the refrigerator and allow it to reach room temperature before preparing it for injection (15–30 minutes).
3. Do not use the syringe after the expiry date which is stated on the outer box or syringe label after “EXP”. If it has expired, return the entire pack to the pharmacy.

The Injection Site(s)

The injection site is the place on the body where you are going to use the pre-filled syringe.

- The recommended site is the front of your thighs. You may also use the lower abdomen, but not the area 5 centimetres around the navel (belly button).
- Choose a different site each time you give yourself an injection.
- Do not inject into areas where the skin is tender, bruised, red, scaly or hard. Avoid areas with scars or stretch marks.

If a caregiver is giving you the injection, the outer upper arms may also be used.

Preparing the Erelzi pre-filled syringe

1. Take the blister out of the refrigerator and leave it unopened for about 15–30 minutes so that it reaches room temperature.
2. When you are ready to use the syringe, open the blister and wash your hands thoroughly with soap and water.
3. Clean the injection site with an alcohol swab.
4. Take the syringe out of the blister.
5. Inspect the syringe. The liquid should be clear or slightly opalescent, colourless or slightly yellowish, and may contain small white or almost translucent particles of protein. This appearance is normal for Erelzi. DO NOT USE if the liquid is cloudy, discoloured, or has large lumps, flakes, or coloured particles. DO NOT USE if the syringe is broken or the needle safety guard is activated. In all these cases, return the entire product pack to the pharmacy.
How to use the Erelzi pre-filled syringe

Carefully remove the needle cap from the syringe. Discard the needle cap. You may see a drop of liquid at the end of the needle. This is normal.

Gently pinch the skin at the injection site and insert the needle as shown. Push the needle all the way in to ensure that the medicine can be fully administered.

Hold the syringe finger flange as shown. **Slowly** press the plunger **as far as it will go**, so that the plunger head is completely between the needle guard wings. Keep the plunger pressed fully down while you hold the syringe in place for 5 seconds.

**Keep the plunger fully depressed** while you carefully lift the needle straight out from the injection site.

Slowly release the plunger and allow the needle safety guard to automatically cover the exposed needle.

There may be a small amount of blood at the injection site. You can press a cotton ball or gauze over the injection site and hold it for 10 seconds. Do not rub the injection site. You may cover the injection site with a small adhesive bandage, if needed.
Disposal Instructions

Dispose of the used syringe in a sharps container (closable, puncture-resistant container). For the safety and health of you and others, needles and used syringes must never be re-used.

Overdose:
Call your doctor if you accidentally inject Erelzi more frequently than instructed.

If you think you have taken too much Erelzi, contact your healthcare professional, hospital emergency department or regional poison control centre immediately, even if there are no symptoms.

Missed Dose:
If you forget to take Erelzi when you are supposed to, contact your doctor to find out when to take your next dose of Erelzi.

What are possible side effects from using Erelzi?
These are not all the possible side effects you may feel when taking Erelzi. If you experience any side effects not listed here, contact your healthcare professional. Please also see Warnings and Precautions.

Like all medicines, Erelzi can cause side effects. Most side effects are mild to moderate. However, some may be serious and require treatment.

Reporting Side Effects

You can report any suspected side effects associated with the use of health products to Health Canada by:

- Visiting the Web page on Adverse Reaction Reporting (http://www.hc-sc.gc.ca/dhp-mps/medeff/report-declaration/index-eng.php) for information on how to report online, by mail or by fax; or
- Calling toll-free at 1-866-234-2345.

NOTE: Contact your health professional if you need information about how to manage your side effects. The Canada Vigilance Program does not provide medical advice.

General Information about Erelzi

Medicines are sometimes prescribed for purposes not mentioned in the Patient Medication Information leaflet. Do NOT use Erelzi for a condition for which it was not prescribed. Do NOT give Erelzi to other people, even if they have the same condition.

Storage:

Erelzi should be refrigerated at 2°C to 8°C. Do NOT freeze Erelzi. Do not use Erelzi beyond the expiration date stamped on the carton, blister or syringe label. DO NOT SHAKE. Store Erelzi in the original carton to protect from light or physical damage.

For convenience, storage of individual syringes at room temperature between 20°C to 25°C for a maximum single period of 28 days is permissible, with protection from light and sources of heat. Once a syringe has been stored at room temperature, it should not be placed back into the refrigerator. If not used within 28 days at room temperature, the syringe should be discarded. Do not store Erelzi in extreme heat or cold. DO NOT FREEZE. Keep out of the reach of children.

If you want more information about Erelzi:

- Talk to your healthcare professional
- Find the full product monograph that is prepared for healthcare professionals and includes this Patient Medication Information by visiting the Health Canada website; the manufacturer’s website www.sandoz.ca, or by calling 1-800-361-3062.

This leaflet was prepared by Sandoz Canada Inc.

Last Revised MARCH-31-2017
READ THIS FOR SAFE AND EFFECTIVE USE OF YOUR MEDICINE

PATIENT MEDICATION INFORMATION

ERELZI (pronounced <eh-rel-zee>)
(etanercept)
Single-use Prefilled SensoReady® Pen

Read this carefully before you start taking Erelzi and each time you get a refill. This leaflet is a summary and will not tell you everything about this drug. Talk to your healthcare professional about your medical condition and treatment and ask if there is any new information about Erelzi.

Erelzi is a biosimilar biologic drug (biosimilar) to the reference biologic drug Enbrel®. A biosimilar is authorized based on its similarity to a reference biologic drug that was already authorized for sale.

<tr>
<th>Serious Warnings and Precautions</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>Serious infections.</strong> There have been cases where patients taking etanercept or other TNF-blocking agents have developed serious infections, including tuberculosis (TB) and infections caused by bacteria, viruses or fungi that have spread throughout their body. Some patients have died from these infections. In very rare cases, hepatitis B recurred in patients with previous hepatitis. If you tend to get infections easily or if you develop an infection while taking etanercept, you should tell your doctor right away.</td>
</tr>
<tr>
<td>• <strong>Malignancies.</strong> There have been cases, sometimes fatal, of unusual cancers in children and teenage patients who started using TNF-blocking agents, including etanercept, at less than 18 years of age.</td>
</tr>
</tbody>
</table>

What is Erelzi used for?
Erelzi is a medicine for treating people with moderate to severe forms of rheumatoid arthritis (RA) or juvenile idiopathic arthritis (JIA). Erelzi is also for treating adults with a type of arthritis called ankylosing spondylitis (AS). RA, JIA, and AS are inflammatory diseases that affect the joints in your body.

How does Erelzi work:
Erelzi is a type of protein called a tumour necrosis factor (TNF) blocker that blocks the action of a substance your body makes called TNF-alpha. TNF-alpha is made by your body’s immune system. People with immune diseases like RA, JIA, as well as patients with AS, have too much TNF-alpha in their bodies, which can cause inflammation and lead to painful, swollen joints. Erelzi can reduce the amount of TNF in the body to normal levels, helping to treat joint damage. In patients with inflammatory arthritis, Erelzi may be effective in reducing signs and symptoms of inflammatory arthritis (such as pain, morning stiffness and fatigue), may help improve your ability to do simple daily activities (such as dressing, walking and climbing stairs), and may help prevent damage to your bones and joints.
When can I expect to see results from taking Erelzi?
Improvement may be seen as early as 1 week after starting etanercept in adults and within 2 weeks in children. In clinical trials, full effect was usually seen by 3 months in both adults and children and was sustained with continued treatment.

What are the ingredients in Erelzi?
Medicinal ingredient: etanercept.
Non-medicinal ingredients: citric acid, L-lysine hydrochloride, sodium chloride, sodium citrate and sucrose.

Erelzi comes in the following dosage forms:
Erelzi Single-use Prefilled Syringes with Needle Guard are available in 25 mg (0.5 mL of a 50 mg/mL solution of etanercept) and 50 mg (1.0 mL of a 50 mg/mL solution of etanercept).
Erelzi Single-use Prefilled SensoReady® Pens are available in 50 mg (1.0 mL of a 50 mg/mL solution of etanercept).

Do not use Erelzi if:
- You should not take Erelzi if you have ever had an allergic reaction to etanercept or any of the ingredients in Erelzi.
- You should not take Erelzi if you have an infection that has spread through your body (sepsis).

To help avoid side effects and ensure proper use, talk to your healthcare professional before you take Erelzi. Talk about any health conditions or problems you may have, including if you:
- have an infection. This could put you at risk for serious side effects from etanercept.
- have symptoms of an infection such as fever, sweats or chills, cough or flu-like symptoms, shortness of breath, blood in your phlegm, weight loss, muscle aches, warm, red, or painful areas on your skin, sores on your body, diarrhea or stomach pain, burning when you urinate or urinate more often than normal, and feel very tired.
- have a history of infections that keep coming back or other conditions — like diabetes, HIV, or a weak immune system — that might increase your risk of infections.
- have tuberculosis (TB), or have been in close contact with someone who has or has had TB. You will need to be evaluated for TB. Your doctor should test you for TB before starting etanercept.
- were born in, lived in, or traveled to countries where there is a risk for getting TB. Ask your doctor if you are not sure.
- live in, have lived in or have traveled to, areas where there is a greater risk for certain kinds of fungal infections (histoplasmosis, coccidioidomycosis, blastomycosis). These infections may develop or become more severe if you take etanercept. If you don't know if you have lived in an area where these infections are common, ask your doctor.
- have or have had hepatitis B.
- have or have had persistent numbness, tingling and muscle weakness or a disease such as multiple sclerosis, Guillain- Barré or a Guillain-Barré -like syndrome, which causes inflammation of the nervous system, either in the brain and spinal cord or nerves going to your hands and feet.
- have been newly diagnosed or are being treated for congestive heart failure.
- are scheduled to have major surgery.
- have recently received or are scheduled to receive a vaccine. All vaccines should be brought up-to-date before starting etanercept. Patients taking etanercept should not receive live vaccines.
- use the medication Kineret® (anakinra), Orencia® (abatacept) or cyclophosphamide (see INTERACTIONS WITH THIS MEDICATION below).
- have been around someone with varicella zoster (chicken pox, shingles)

Know the medicines you take. Keep a list of them to show your doctor and pharmacist each time you get a new medicine.

Your doctor should monitor you closely for signs and symptoms of TB during treatment with etanercept even if you have tested negative for TB. If you develop any of the symptoms of TB (a dry cough that doesn’t go away, weight loss, fever, night sweats) call your doctor.

If you are not sure or have any questions about any of this information, ask your doctor.

Other warnings you should know about:

All medicines have side effects. Medicines, like Erelzi, that affect your immune system can cause serious side effects. The possible serious side effects include:

- **Nervous system diseases.** There have been rare cases of disorders that affect the nervous system of people taking etanercept or other TNF blockers, such as multiple sclerosis, seizures or inflammation of the nerves of the eyes. Signs that you could be experiencing a problem affecting your nervous system include: numbness or tingling throughout your body, problems with your vision, weakness in your arms and/or legs, and dizziness.

- **Blood problems.** In some patients the body may fail to produce enough of the blood cells that can help your body fight infections or help you to stop bleeding. This can lead to death. If you develop a fever that doesn’t go away, bruise or bleed very easily or look very pale or feel faint, call your doctor right away. Your doctor may decide to stop treatment. Some people have also had symptoms that resemble lupus (rash on your face and arms that gets worse in the sun) that may go away when you stop taking etanercept.

- **Heart problems.** You should also tell your doctor if you have ever been treated for heart failure. If you have, your doctor may choose not to start you on etanercept, or may want to monitor you more closely. Symptoms include shortness of breath or swelling of your ankles and feet.

- **Allergic reactions.** Some patients have had allergic reactions to etanercept. If you develop a severe rash, swollen face or difficulty breathing while taking etanercept, call your doctor right away.

- **Malignancies.** Patients with inflammatory diseases including RA or AS, particularly those with highly active disease, may be at higher risk for lymphoma (a type of cancer). For children and adults taking TNF-blocker medicines including etanercept, the chances of getting lymphoma or other cancers may increase. Whether treatment with etanercept might influence the development and course of malignancies in adults is unknown.

- **Liver problems** (autoimmune hepatitis). Liver problems can happen in people who use TNF blocker medicines, including etanercept. These problems can lead to liver failure
and death. Call your doctor right away if you have any of these symptoms: feel very
tired, skin or eyes look yellow, poor appetite or vomiting, pain on the right side of your
stomach (abdomen). These symptoms may occur several months after starting and even
after etanercept has been stopped.

- **Serious infections.** Etanercept can lower the ability of your immune system to fight
infections. So, taking etanercept can make you more prone to getting infections or make
any infection that you may have worse. Some people have serious infections while
taking etanercept including infections that spread through the body such as tuberculosis
(TB), legionellosis (usually a bacterial pneumonia), and listeriosis (usually from
contaminated food). Other infections caused by viruses, fungi, bacteria or parasites may
occur. Some people have died from these infections.

**What are the common side effects?**
In studies comparing etanercept to placebo (inactive injection), side effects that occurred more
frequently in patients treated with etanercept were:
- Reactions where the injection was given. These reactions are usually mild and include
  redness, swelling, itching, or bruising. These usually go away within 3 to 5 days. If you
  have pain, redness or swelling around the injection site that doesn’t go away or gets
  worse, call your doctor.
- Upper respiratory infections (sinus infections)
- Headaches

**Can I take Erelzi if I am pregnant or breastfeeding?**
Etanercept has not been studied in pregnant women or nursing mothers, therefore its effects on
pregnant women or nursing babies are not known.

You should tell your doctor if you are pregnant, become pregnant or are thinking about
becoming pregnant. If you took etanercept during pregnancy, talk to your doctor prior to
administration of live vaccines to your infant.

Etanercept can pass into breast milk. You and your doctor should decide if you will take
etanercept or breastfeed. You should not do both.

If you are not sure or have any questions about any of this information, ask your doctor.

**Tell your healthcare professional about all the medicines you take, including any drugs,
vitamins, minerals, natural supplements or alternative medicines.**

It is important that you tell your doctor about any other medicines (for example, high blood
pressure medicine) you are taking for other conditions before you start taking etanercept. You
should also tell your doctor about any over-the-counter drugs, herbal medicines and vitamin and
mineral supplements you are taking.

If you have diabetes and are taking medication to control your diabetes, your doctor may decide
you need less anti-diabetic medicine while taking etanercept.

**Can I take Erelzi if I am taking other medicines for my RA, JIA, AS or other conditions?**
In adults, Erelzi can be used in combination with methotrexate. However, little is known of the
interaction of etanercept with methotrexate and other drugs in children with juvenile idiopathic
arthritis.
The following may interact with Erelzi:

- Taking etanercept with Kineret® (anakinra) is not recommended because this may increase your risk of getting a serious infection.
- Taking etanercept with Orecia® (abatacept) is not recommended because this may increase your risk for serious side effects.
- Taking etanercept with cyclophosphamide (used to treat cancer or immune diseases) is not recommended. You may have a higher chance for getting certain cancers when taking Erelzi with cyclophosphamide.

How to take Erelzi:

Usual dose:
Erelzi is given as an injection under the skin.

You may continue to use other medicines that help treat your condition while taking Erelzi, such as non-steroidal anti-inflammatory drugs (NSAIDs) and prescription steroids, as recommended by your doctor.

If you have RA or AS, the recommended dose of Erelzi for adults is 50 mg per week given as one injection using a 50 mg single-use prefilled SensoReady® Pen.

The recommended dose of Erelzi for children with juvenile idiopathic arthritis is based on the child’s body weight. Your child’s doctor will tell you the correct amount of Erelzi your child should take and will prescribe an appropriate strength of etanercept. Erelzi is available for treatment of children and adolescents weighing 63 kg (138 pounds) or more.

Make sure you have been shown how to inject Erelzi before you do it yourself. Someone you know can also help you with your injection. Remember to take this medicine just as your doctor has told you and do not miss any doses.

Instructions for Use: Erelzi (etanercept) SensoReady® pen
Solution for injection in a pre-filled pen

Read ALL the way through these instructions before injecting. These instructions are to help you to inject correctly using the Erelzi SensoReady pen. It is important not to try to inject yourself until you have been trained by your doctor, nurse or pharmacist.

Your Erelzi (etanercept) SensoReady® pen:

Erelzi SensoReady® pen shown with the cap removed. Do not remove the cap until you are ready to inject.
Store your boxed pen in a **refrigerator**, between 2°C to 8°C and **out of the reach of children**.

- **Do not freeze** the pen.
- **Do not shake** the pen.
- Do not use the pen if it has been **dropped** with the cap removed.

For a more comfortable injection, take the pen out of the refrigerator **15-30 minutes before injecting** to allow it to reach room temperature.

**What you need for your injection:**

- **Included in the carton:**
  - A new and unused Erelzi SensoReady® pen

- **Not included in the carton:**
  - Alcohol swab
  - Cotton ball or gauze
  - Sharps disposal container

**Before your injection:**

1. **Important safety checks before you inject:**
   - The solution should be clear or slightly opalescent, colorless or slightly yellowish, and may contain small white or almost transparent particles of protein. This appearance is normal for Erelzi.
   - **Do not use** if the liquid is cloudy, discolored, or has large lumps, flakes, or colored particles.
   - **Do not use** the pen if the **expiry date** has passed.
   - **Do not use** if the **safety seal** has been broken.
   - Contact your pharmacist if the pen fails any of these checks.

2a. **Choose your injection site:**
   - The recommended site is the front of the thighs. You may also use the lower abdomen, but **not** the area 5 centimetres around the navel (belly button).
   - Choose a different site each time you give yourself an injection.
   - Do not inject into areas where the skin is tender, bruised, red, scaly or hard. Avoid areas with scars or stretch marks.

2b. **Caregivers and healthcare professionals only:**
   - If a **caregiver** or **healthcare professional** is giving you your injection, they may also inject into your outer upper arm.
3. Cleaning your injection site:
- Wash your hands with soap and hot water.
- Using a circular motion, clean the injection site with the alcohol swab. Leave it to dry before injecting.
- Do not touch the cleaned area again before injecting.

4. Removing the cap:
- Only remove the cap when you are ready to use the pen.
- Twist off the cap in the direction of the arrows.
- Once removed, throw away the cap. Do not try to re-attach the cap.
- Use the pen within 5 minutes of removing the cap.

5. Holding your pen:
- Hold the pen at 90 degrees to the cleaned injection site.

YOU MUST READ THIS BEFORE INJECTING.
During the injection you will hear 2 loud clicks.
The 1st click indicates that the injection has started. Several seconds later a 2nd click will indicate that the injection is almost finished.
You must keep holding the pen firmly against your skin until you see a green indicator fill the window and stop moving.

6. Starting your injection:
- Press the pen firmly against the skin to start the injection.
- The 1st click indicates the injection has started.
- Keep holding the pen firmly against your skin.
- The green indicator shows the progress of the injection.
7. Completing your injection:
   - Listen for the 2nd click. This indicates the injection is almost complete.
   - Check the green indicator fills the window and has stopped moving.
   - The pen can now be removed.

After your injection:

8. Check the green indicator fills the window:
   - This means the medicine has been delivered. Contact your doctor if the green indicator is not visible.
   - There may be a small amount of blood at the injection site. You can press a cotton ball or gauze over the injection site and hold it for 10 seconds. Do not rub the injection site. You may cover the injection site with a small adhesive bandage, if needed.

9. Disposing of your Erelzi SensoReady® pen:
   - Dispose of the used pen in a sharps disposal container (i.e. a puncture-resistant closable container, or similar).
   - Never try to re-use your pen.

Overdose:
Call your doctor if you accidentally inject Erelzi more frequently than instructed.

If you think you have taken too much Erelzi, contact your healthcare professional, hospital emergency department or regional poison control centre immediately, even if there are no symptoms.

Missed Dose:
If you forget to take Erelzi when you are supposed to, contact your doctor to find out when to take your next dose of Erelzi.

What are possible side effects from using Erelzi?
These are not all the possible side effects you may feel when taking Erelzi. If you experience any side effects not listed here, contact your healthcare professional. Please also see Warnings and Precautions.

Like all medicines, Erelzi can cause side effects. Most side effects are mild to moderate. However, some may be serious and require treatment.
