INDICATIONS AND CLINICAL USE

Hypertension

APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR (metoprolol tartrate) is indicated for mild or moderate hypertension. Usually combined with other antihypertensive agents (thiazide diuretics), it may be tried alone when the physician judges that a beta-blocker, rather than a diuretic, should be the initial treatment.

Combining metoprolol tartrate with a diuretic or peripheral vasodilator has been found to be compatible and generally more effective than metoprolol tartrate alone. Limited experience with other antihypertensive agents has not shown evidence of incompatibility with metoprolol tartrate.

APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR is not recommended for the emergency treatment of hypertensive crises.

Angina Pectoris

APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR is indicated for the long-term treatment of angina pectoris due to ischemic heart disease.

Myocardial Infarction

APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR is indicated in the treatment of hemodynamically stable patients with definite or suspected acute myocardial infarction, to reduce cardiovascular mortality.

Alternatively, in patients with proven myocardial infarction, oral treatment can begin within 3 to 10 days of the acute event (see Dosage and Administration). Data are not available as to whether benefit would ensue if the treatment is initiated later.

Clinical trials have shown that patients with unconfirmed myocardial infarction received no benefit from early metoprolol tartrate therapy.

Geriatrics:
Caution is indicated when using APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR in elderly patients. An excessively pronounced decrease in blood pressure or pulse rate may cause the blood supply to vital organs to fall to inadequate levels.

Pediatrics:
No pediatric studies have been performed. The safety and efficacy of APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR in pediatric patients have not been established.
CONTRAINDICATIONS

APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR should not be used in the presence of:

- Known hypersensitivity to metoprolol and derivatives, APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR components, or hypersensitivity to other beta-blockers (cross-sensitivity between beta-blockers can occur)
- Sinus bradycardia
- Sick sinus syndrome
- Second and third degree A-V block
- Right ventricular failure secondary to pulmonary hypertension
- Overt heart failure
- Cardiogenic shock
- Severe peripheral arterial circulatory disorders
- Anesthesia with agents that produce myocardial depression, (e.g., ether)
- Untreated pheochromocytoma
- The intravenous form is also contraindicated in the presence of asthma and other obstructive respiratory diseases (for oral treatment, see Precautions – Bronchospastic Diseases).

Myocardial Infarction Patients - Additional Contraindications

APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR is contraindicated in patients with a heart rate < 45 beats/min; significant heart block greater than first degree (PR interval ≥ 0.24 s); systolic blood pressure < 100 mmHg; or moderate to severe cardiac failure (see Warnings and Precautions).
WARNINGS AND PRECAUTIONS

General

Cardiovascular system: Special caution should be exercised when administering APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR to patients with a history of heart failure. Sympathetic stimulation is a vital component supporting circulatory function in congestive heart failure, and inhibition with β-blockade always carries the potential hazard of further depressing myocardial contractility and precipitating cardiac failure. The positive inotropic action of digitalis may be reduced by the negative inotropic effect of metoprolol tartrate when the two drugs are used concomitantly. The effects of β-blockers and digitalis are additive in depressing A-V conduction. This also applies to combinations with calcium-antagonists of the verapamil type or some antiarrhythmics (see Drug Interactions).

In patients without a history of cardiac failure, continued depression of the myocardium over a period of time can, in some cases, lead to cardiac failure and/or hypotension (systolic blood pressure ≤ 90 mmHg). Therefore, at the first sign or symptom of impending cardiac failure, patients should be fully digitalized and/or given a diuretic and the response observed closely. If cardiac failure continues, despite adequate digitalization and diuretic therapy, APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR therapy should be reduced or withdrawn.

Cardiovascular

Severe Sinus Bradycardia: Severe sinus bradycardia may occur after β₁-adrenergic receptor blockade with metoprolol tartrate because of unopposed vagal activity. Very rarely a pre-existing A-V conduction disorder of moderate degree may become aggravated, possibly leading to A-V block. In such cases, dosage should be reduced or gradually withdrawn. Atropine, isoproterenol or dobutamine should be considered in patients with acute myocardial infarction.

Prinzmetal's angina: Beta-blockers may increase the number and duration of angina attacks in patients with Prinzmetal's angina (variant angina pectoris).

Peripheral Circulatory Disorders: Metoprolol may aggravate the symptoms of peripheral arterial circulatory disorders, mainly due to its blood pressure lowering effect.

Myocardial Infarction - Additional Warnings

Acute Intervention: During acute intervention in myocardial infarction, intravenous metoprolol should only be used by experienced staff under circumstances where resuscitation and monitoring equipment is available.

Cardiac Failure: Depression of the myocardium with APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR may lead to cardiac failure (see general Warnings above). Special caution should be exercised when administering APO-
METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR to patients with a history of cardiac failure or those with minimal cardiac reserve. Should failure occur, treatment should be as described in Warnings.

**Severe Sinus Bradycardia:** Severe sinus bradycardia may occur with APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR use (see general Warnings above). Acute myocardial infarction (particularly inferior infarcts) may significantly decrease sinus rate. If the rate falls below 40 beats/min, especially with signs of decreased cardiac output, administer atropine (0.25 to 0.5 mg) intravenously. If atropine treatment is unsuccessful, discontinue APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR and consider cautious administration of isoproterenol or installation of a cardiac pacemaker.

**A-V Conduction:** APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR slows A-V conduction and may produce significant first- (PR interval $\geq 0.24$ sec), second-, or third-degree heart block. Acute myocardial infarction may also produce heart block. If heart block occurs, discontinue APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR and administer atropine (0.25-0.5 mg) intravenously. If atropine treatment is unsuccessful, consider cautious administration of isoproterenol or installation of a cardiac pacemaker. Because of their negative effect on atrioventricular conduction, beta-blockers, including APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR should only be given with caution to patients with first degree atrioventricular block.

**Hypotension:** If hypotension (systolic blood pressure $\leq 90$ mmHg) occurs, APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR should be discontinued, and the hemodynamic status of the patient and the extent of myocardial ischemia carefully assessed. Invasive monitoring of central venous, pulmonary capillary wedge and arterial pressures may be required. Appropriate therapy with fluids, positive inotropic agents, balloon counterpulsation, or other treatment modalities should be instituted. If hypotension is associated with sinus bradycardia or A-V block, treatment should be directed at reversing these (see above).

**Abrupt withdrawal**

Patients with angina should be warned against abrupt discontinuation of APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR. There have been reports of severe exacerbation of angina, and of myocardial infarction or ventricular arrhythmias occurring in patients with angina pectoris, following abrupt discontinuation of b-blocker therapy. The last two complications may occur with or without preceding exacerbation of angina pectoris. Therefore, when discontinuation of APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR is planned in patients with angina pectoris or previous myocardial infarction, the dosage should be gradually reduced over a period of about two weeks. The patient should be carefully observed. The same frequency of administration should be maintained. In situations of greater urgency, metoprolol tartrate therapy should be discontinued stepwise and with closer observation. If angina markedly worsens or acute coronary insufficiency develops, it
is recommended that treatment with APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR be reinstituted promptly, at least temporarily.

Patients should be warned against interruption or discontinuation of therapy without the physician's advice. Because coronary artery disease is common and may be unrecognized, it is prudent not to discontinue APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR therapy abruptly even in patients treated only for hypertension.

**Endocrine and Metabolism**

**Thyrotoxicosis:** Although metoprolol has been used successfully for the symptomatic (adjuvant) therapy of thyrotoxicosis, possible deleterious effects from long-term use of metoprolol tartrate have not been adequately appraised. ß-blockade may mask the clinical signs of continuing hyperthyroidism or its complications, and give a false impression of improvement. Therefore, abrupt withdrawal of metoprolol tartrate may be followed by an exacerbation of the symptoms of hyperthyroidism, including thyroid storm.

**Diabetic patients:** APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR should be administered cautiously to patients spontaneously hypoglycemic or diabetic patients who are receiving insulin or oral hypoglycemic agents. ß-adrenergic receptor blockers, including APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR affect glucose metabolism and may mask the premonitory signs and symptoms of acute hypoglycemia, such as tachycardia. In patients with insulin or non-insulin dependent diabetes, especially labile diabetes, or with a history of spontaneous hypoglycaemia, beta-blockade may result in the loss of diabetic control and delayed recovery from hypoglycaemia. The dose of insulin or oral hypoglycaemic agent may need adjustment. Diabetic patients receiving APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR should be monitored to ensure that diabetes control is maintained.

**Pheochromocytoma:** Where a ß-blocker is prescribed for a patient known to be suffering from a pheochromocytoma, an alpha-blocker should be given concomitantly and only after the alpha-blocker has been initiated.

**Hepatic/Biliary/Pancreatic**

Metoprolol tartrate is mainly eliminated by means of hepatic metabolism (see *Action and Clinical pharmacology - Pharmacokinetics*).

**Hepatic impairment:** may increase the systemic bioavailability of metoprolol and reduce its total clearance, leading to increased plasma concentrations. Therefore, APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR should be used with caution in patients with impaired liver function. Liver function tests should be performed at regular intervals during long-term treatment (see *Actions and Clinical Pharmacology - Pharmacokinetics*). Therefore, hepatic impairment may increase the systemic bioavailability of metoprolol and reduce its total clearance, leading to increased plasma concentrations. Therefore, dose adjustment and regular monitoring of hepatic function are advised in patients with mild to moderate hepatic impairment.

Patients with severe hepatic impairment should be treated with caution i.e. lower initial and
maintenance doses as well as regular monitoring of hepatic function, as they are more sensitive to therapeutic effects/adverse effects of drugs.

**Interactions**

Calcium channel blocker of the verapamil (phenylalkylamine) type should not be given intravenously to patients receiving metoprolol tartrate because there is a risk of cardiac arrest in this situation (see *Drug Interactions*). Patients taking an oral calcium channel blocker of the verapamil type in combination with APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR should be closely monitored. See the complete list of observed and potential drug-drug and other drug interactions with metoprolol tartrate in *Drug Interactions* section.

**Peripheral vascular disease:**
Beta-blockade may impair the peripheral circulation and exacerbate the symptoms of peripheral vascular disease (see *Contraindications*).

**Peri-Operative Considerations**

*Anesthesia and Surgery:* The necessity or desirability of withdrawing beta-blocking agents prior to major surgery is controversial. The impaired ability of the heart to respond to reflex adrenergic stimuli may augment the risks of general anaesthesia and surgical procedures. The benefits of continuing a treatment with a beta-blocker should be balanced against the risk of withdrawing it in each patient. However, care should be taken to avoid using anesthetic agents that may depress the myocardium. Vagal dominance, if it occurs, may be corrected with atropine (1 to 2 mg i.v.).

In patients receiving beta-blocker therapy, inhalation anaesthetics may enhance the cardiodepressant effect. Beta-blockade may have beneficial effects in decreasing the incidence of arrhythmias and myocardial ischaemia during anaesthesia and the postoperative period. It is currently recommended that maintenance beta-blockade be continued peri-operatively. The anaesthetist must be made aware of beta-blockade because of the potential for interactions with other drugs, resulting in severe bradyarrhythmias and hypotension, the decreased reflex ability to compensate for blood loss, hypovolaemia and regional sympathetic blockade, and the increased propensity for vagal-induced bradycardia. Incidents of protracted severe hypotension or difficulty restoring normal cardiac rhythm during anaesthesia have been reported.

Modern inhalational anaesthetic agents are generally well tolerated, although older agents (ether, cyclopropane, methoxyflurane, trichlorethylene) were sometimes associated with severe circulatory depression in the presence of beta-blockade. If it is thought necessary to withdraw beta-blocker therapy before surgery, this should be done gradually and completed about 48 hours before anaesthesia.

Since metoprolol is a competitive inhibitor of β-adrenoceptor agonists, its effects may be reversed, if necessary, by sufficient doses of such agonists as isoproterenol or dobutamine.
Renal:

**Renal impairment:** In patients with severe renal disease, haemodynamic changes following beta-blockade may impair renal function further. Beta-blockers which are excreted mainly by the kidney may require dose adjustment and safety monitoring in patients with severe renal impairment, including renal failure.

Respiratory

**Bronchospastic Diseases:** In general, patients with bronchospastic diseases should not receive beta-blockers, including APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR. However, because of its relative beta_{1}-selectivity, metoprolol tartrate may be used with caution in patients with asymptomatic bronchospastic disease who do not respond to, or cannot tolerate, other antihypertensive treatment. Since beta_{1}-selectivity is not absolute, a beta_{2}-stimulating agent should preferably be administered concomitantly, and the lowest possible dose of metoprolol tartrate should be used. In these circumstances it would be prudent initially to administer APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR in smaller doses three times daily, instead of larger doses two times daily, to avoid the higher plasma levels associated with the longer dosing interval (**see Dosage and Administration**).

Because it is unknown to what extent beta_{2}-stimulating agents may exacerbate myocardial ischemia and the extent of infarction, these agents should not be used prophylactically in patients with proven or suspected acute myocardial infarction. If bronchospasm not related to congestive heart failure occurs, APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR should be discontinued. A theophylline derivative or a beta_{2}-agonist may be administered cautiously, depending on the clinical condition of the patient. Both theophylline derivatives and beta_{2}-agonists may produce serious cardiac arrhythmias.

Sensitivity/Resistance

**Anaphylactic reactions:** There may be increased difficulty in treating an allergic type reaction in patients on beta-blockers. Whenever possible, beta-blockers, including APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR, should be avoided in patients who are at risk of anaphylaxis. In these patients, the reaction may be more severe due to pharmacologic effects of the beta-blockers and problems with fluid changes. Epinephrine should be administered with caution since it may not have its usual effects in the treatment of anaphylaxis. On the one hand, larger doses of epinephrine may be needed to overcome the bronchospasm, while on the other these doses can be associated with excessive alpha-adrenergic stimulation with consequent hypertension, reflex bradycardia and heart block and possible potentiation of bronchospasm. Alternatives to the use of large doses of epinephrine include vigorous supportive care such as fluids and the use of beta-agonists including parenteral salbutamol or isoproterenol, to overcome bronchospasm and norepinephrine to overcome hypotension.

Skin:

**Oculomucocutaneous Syndrome:** Various skin rashes and conjunctival xerosis have been reported with beta-blockers, including metoprolol tartrate. Oculomucocutaneous syndrome, a severe syndrome whose signs include conjunctivitis sicca and psoriasiform rashes, otitis, and sclerosing serositis has occurred with the chronic use of one beta-adrenergic receptor-blocking agent.
(practolol). This syndrome has not been observed with metoprolol tartrate or any other such agent. However, physicians should be alert to the possibility of such reactions and should discontinue treatment in the event that they occur.

**Special Populations**

**Women of child-bearing potential:** Upon confirming the diagnosis of pregnancy, women should immediately inform the doctor and stop gradually taking the drug. The use of any drug in patients of child-bearing potential requires that the anticipated benefit be weighed against the possible hazards.

**Pregnant Women:** There is a limited amount of data on the use of metoprolol in pregnant women. Metoprolol crosses the placental barrier. Since metoprolol tartrate has not been studied in human pregnancy, the drug should not be given to pregnant women.

**Nursing Women:** Metoprolol is excreted in breast milk. If drug use is essential, patients should stop nursing.

**Pediatrics:** No pediatric studies have been performed. The safety and efficacy of metoprolol tartrate in children has not been established.

**Geriatrics:** Caution is indicated when using APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR in elderly patients. An excessively pronounced decrease in blood pressure or pulse rate may cause the blood supply to vital organs to fall to inadequate levels. Lower starting and maintenance doses and safety monitoring are advised in these patients (see *Indications and Clinical use, Dosage and Administration, and Action and Clinical Pharmacology-Pharmacokinetics-Special populations*).

**Driving and using machines**

Dizziness, fatigue or visual impairment may occur during treatment with APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR (see *Adverse Drug reactions*) and may adversely affect the patient’s ability to drive or use machines.

Patients should be advised to avoid operating automobiles and machinery or engaging in other tasks requiring alertness until the patient's response to APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR therapy has been determined.

**ADVERSE REACTIONS**

**Adverse Drug Reaction Overview**

The most common adverse events reported are exertional tiredness, gastrointestinal disorders, and disturbances of sleep patterns. The most serious adverse events reported are congestive heart failure, bronchospasm and hypotension.

Abnormal Hematologic and Clinical Chemistry Findings

Clinical Laboratory

The following laboratory parameters have been elevated on rare occasions: transaminases, BUN, alkaline phosphatase and bilirubin.

Hematology

Isolated cases of thrombocytopenia and leucopenia.

Post Market Adverse Drug Reactions

The following adverse reactions have been derived from post-marketing experience with metoprolol tartrate via spontaneous case reports and literature cases. Because these reactions are reported voluntary from a population of uncertain size and are subject to confounding factors, it is not possible to reliably estimate their frequency which is therefore categorized as not known. Adverse drug reactions are listed according to system organ classes in MedDRA. Within each system organ class, ADRs are presented in order of decreasing seriousness.

Nervous system disorders
Confusional state

Metoprolol | Ref | Effect | Clinical comment
---|---|---|---
Sympathomimetics | C | hypertension | Concomitant administration of sympathomimetic drugs such as adrenaline, noradrenaline, isoprenaline, ephedrine, phenylephrine, phenylpropanolamine, and xanthine derivatives (including antitussives or nose and eye drops) with a $\beta$-blocker may enhance the pressor response resulting in hypertension due to mutual inhibition of therapeutic effects.

**Drug-Food Interactions**

Food enhances the bioavailability of an oral dose of metoprolol by approximately 20-40%. Indeed, food intake affects the pharmacokinetics of metoprolol leading to increased exposure (AUC) and a higher maximum plasma concentration ($C_{\text{max}}$) (see *Actions and Clinical Pharmacology*). Hence, in order to minimize the effect variations within the individual, it is recommended that the drug should be administered with or immediately following meals.

In one clinical study with metoprolol immediate release formulation, it was found that $C_{\text{max}}$ and AUC were higher by about 32% and 38%, respectively, when administered after standard breakfast as compared to fasting condition. The study recommended that the drug should be administered with or immediately following meals to minimize the variations within an individual.

**Drug-Herb Interactions**

The interaction of metoprolol with herbal medications or supplements has not been studied.

**Drug-Laboratory Interactions**

No data suggest that metoprolol interferes with laboratory tests.

**Drug-Lifestyle Interactions**

Dizziness, fatigue or visual impairment may occur during treatment with APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR (see *Adverse Drug reactions*) and may adversely affect the patient’s ability to drive or use machines.

**DOSAGE AND ADMINISTRATION**

**Dosing Considerations**

*Special Note to Pharmacist:* Splitting APO-METOPROLOL (Type L) tablets is not recommended since the film coating will be damaged.
Slow-release APO-METOPROLOL SR Tablets

Treatment must always be initiated and individual titration of dosage carried out using the regular tablets. The SR formulations may be preferred for maintenance because of the convenience of once-daily administration. APO-METOPROLOL SR tablets should be taken in the morning and swallowed whole.

APO-METOPROLOL SR 100 mg is intended for maintenance dosing in those patients requiring 100 mg metoprolol tartrate per day.

APO-METOPROLOL SR 200 mg is intended for maintenance dosing in those patients requiring doses of 200 mg per day.

Tablet residue in feces: after the active substance has diffused out of the insoluble core of the APO-METOPROLOL SR Tablet, the tablet residue is excreted in a softened form and may be found in the feces.

Recommended Dose and Dosage Adjustment

Hypertension

APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR is usually used in conjunction with other antihypertensive agents, particularly a thiazide diuretic, but may be used alone (see Indications).

The dose must always be adjusted to the individual requirements of the patient, in accordance with the following guidelines.

APO-METOPROLOL / APO-METOPROLOL (Type L) treatment should be initiated with doses of 50 mg b.i.d. If an adequate response is not seen after one week, dosage should be increased to 100 mg b.i.d. In some cases the daily dosage may need to be increased by further 100 mg increments at intervals of not less than two weeks up to a maximum of 200 mg b.i.d., which should not be exceeded. The usual maintenance dose is within the range of 100 to 200 mg daily.

When metoprolol tartrate is combined with another antihypertensive agent which is already being administered, metoprolol tartrate should be added initially at a dose of 50 mg b.i.d. After one or two weeks the daily dosage may be increased if required, in increments of 100 mg, at intervals of not less than two weeks, until adequate blood pressure control is obtained.

Given the interactions of metoprolol tartarte with food, it is recommended that the drug should be administered with or immediately following meals (see Action and Clinical Pharmacology - Pharmacokinetics, Drug Interactions-Drug-Food interactions).
Angina Pectoris

The recommended dosage range for APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR in angina pectoris is 100-400 mg per day in divided doses. Treatment should be initiated with 50 mg b.i.d. for the first week. If response is not adequate, the daily dosage should be increased by 100 mg for the next week. The usual maintenance dose is 200 mg/day. The need for further increases should be closely monitored at weekly intervals and the dosage increased in 100 mg increments to a maximum of 400 mg/day in two or three divided doses. A metoprolol tartrate dose of 400 mg/day should not be exceeded.

Myocardial Infarction

In addition to the usual contraindications:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Systolic Blood Pressure</td>
<td>≥ 100 mmHg</td>
</tr>
<tr>
<td>Heart Rate *</td>
<td>≥ 45 beats per minute</td>
</tr>
<tr>
<td>PR Interval</td>
<td>&lt; 0.24 seconds</td>
</tr>
<tr>
<td>Rales*</td>
<td>&lt; 10 cm</td>
</tr>
<tr>
<td>Adequate peripheral circulation</td>
<td></td>
</tr>
</tbody>
</table>

*Extreme caution should be exercised when giving intravenous metoprolol to patients with heart rate between 45 and 60 and/or pulmonary rales less than 10 cm.

Therapy should be discontinued in patients if the heart rate drops below 45 or the systolic blood pressure drops below 100 mmHg.

Early Treatment

During the early phase of definite or suspected acute myocardial infarction, treatment with metoprolol tartrate can be initiated as soon as possible after the patient's arrival in the hospital. Such treatment should be initiated in a coronary care or similar unit immediately after the patient's hemodynamic condition has stabilized.

Treatment in this early phase should begin with the intravenous administration of three bolus injections of 5 mg of metoprolol tartrate each. The injections should be given at approximately 2-minute intervals. During the intravenous administration of metoprolol tartrate, blood pressure, heart rate, and electrocardiogram should be carefully monitored. If any of the injections are associated with adverse cardiovascular effects, intravenous administration should be stopped immediately and the patient should be observed carefully and appropriate therapy instituted.

In patients who tolerate the full intravenous dose (15 mg), APO-METOPROLOL/APO-METOPROLOL (Type L) tablets, 50 mg every 6 hours, should be initiated 15 minutes after the
last intravenous dose and continued for 48 hours. Thereafter, patients should receive a maintenance dosage of 100 mg twice daily (see Late Treatment below).

Patients who appear not to tolerate the full intravenous dose should be started on either 25 mg or 50 mg every 6 hours (depending on the degree of intolerance) 15 minutes after the last intravenous dose or as soon as their clinical condition allows. In patients with severe intolerance, treatment with APO-METOPROLOL/APO-METOPROLOL (Type L) should be discontinued (see Warnings and Precautions).

**Late Treatment** (For proven myocardial infarction patients only)

Patients with contraindications to treatment during the early phase of myocardial infarction, patients who appear not to tolerate the full early treatment, and patients in whom the physician wishes to delay therapy for any other reason should be started on APO-METOPROLOL/APO-METOPROLOL (Type L) tablets, 100 mg twice daily, as soon as their clinical condition allows. Treatment can begin within 3-10 days of the acute event. Therapy should be continued for at least 3 months. Although the efficacy of treatment with metoprolol tartrate beyond 6 months has not been conclusively established data from studies with other β-blockers suggest that the treatment should be continued for 1-3 years.

**Special populations**

**Pediatric patients**
No pediatric studies have been performed. The safety and efficacy of metoprolol tartrate in pediatric patients have not been established.

**Renal impairment**
No dose adjustment of metoprolol tartrate is required in patients mild to moderate renal impairment. Caution and regular monitoring of renal function are required in patients with severe renal impairment (see Action and Clinical Pharmacology -Pharmacokinetics-Special populations).

**Hepatic impairment**
Metoprolol tartrate blood levels are likely to increase substantially in patients with mild to moderate hepatic impairment. Therefore, metoprolol tartrate should be initiated at low doses with cautious gradual dose titration according to clinical response and safety monitoring. Patients with severe hepatic impairment should be treated with caution i.e. lower initial and maintenance doses as well as regular monitoring of hepatic function, as they are more sensitive to therapeutic effects/adverse effects of drugs (see Action and Clinical Pharmacology -Pharmacokinetics-Special populations).

**Geriatric patients (>65 years)**
APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR should be given with caution in geriatric patients due to increased likelihood of adverse events. Lower starting and maintenance doses and safety monitoring are recommended (see Action and Clinical Pharmacology-Pharmacokinetics-Special populations).
OVERDOSAGE

Symptoms

The most common signs to be expected with overdosage of a \( \beta \)-adrenoreceptor agent are hypotension, bradycardia, congestive heart failure, myocardial infarction, bronchospasm and hypoglycemia. Atrioventricular block, cardiogenic shock and cardiac arrest may develop. In addition, impairment of consciousness (or even coma), convulsions, nausea, vomiting and cyanosis and death may occur.

Concomitant ingestion of alcohol, antihypertensives, quinidine, or barbiturates aggravate the signs and symptoms.

The first manifestations of overdosage set in 20 minutes to 2 hours after drug administration.

Management

If overdosage occurs, in all cases therapy with APO-METOPROLOL/APO-METOPROLOL (Type L)/ APO-METOPROLOL SR should be discontinued, the patient hospitalized and observed closely. Remove any drug remaining in the stomach by induction of emesis or gastric lavage.

Other clinical manifestations of overdose should be managed symptomatically based on modern methods of intensive care.

For management of a suspected drug overdose, contact your regional Poison Control Centre immediately.

Bradycardia and Hypotension: Initially 1 to 2 mg of atropine sulfate should be given intravenously. If a satisfactory effect is not achieved, norepinephrine or dopamine may be administered after preceding treatment with atropine. (See Precaution concerning the use of epinephrine in \( \beta \)-blocked patients.) In case of hypoglycemia glucagon (1 to 10 mg) can be administered.

Heart Block (second- or third-degree): Isoproterenol or transvenous cardiac pacemaker.
1. Congestive Heart Failure: Conventional therapy.
2. Bronchospasm: Intravenous aminophylline or a b2-agonist.
3. Hypoglycemia: Intravenous glucose.

It should be remembered that metoprolol is a competitive antagonist of isoproterenol and hence large doses of isoproterenol can be expected to reverse many of the effects of excessive doses of metoprolol. However, the complications of excess isoproterenol, e.g. hypotension and tachycardia, should not be overlooked.
**Mechanism of Action**
Metoprolol is a \(\beta\)-adrenergic receptor-blocking agent. *In vitro* and *in vivo* animal studies have shown that it has a preferential effect on the \(\beta_1\)-adrenoreceptors, chiefly located in cardiac muscle. This preferential effect is not absolute, however, and at higher doses, metoprolol tartrate also inhibits \(\beta_2\)-adrenoreceptors, chiefly located in the bronchial and vascular musculature. Metoprolol has no membrane-stabilizing or partial agonism (intrinsic sympathomimetic) activities. It is used in the treatment of hypertension, angina pectoris and to reduce mortality in patients with myocardial infarction.

The mechanism of the antihypertensive effect has not been established. Among the factors that may be involved are:

a) competitive ability to antagonize catecholamine-induced tachycardia at the \(\beta\)-receptor sites in the heart, thus decreasing heart rate, cardiac contractility and cardiac output;
b) inhibition of renin release by the kidneys;
c) inhibition of the vasomotor centres.

By blocking catecholamine-induced increases in heart rate, in velocity and extent of myocardial contraction, and in blood pressure, metoprolol reduces the oxygen requirements of the heart at any given level of effort, thus making it useful in the long-term management of angina pectoris. However, in patients with heart failure, \(\beta\)-adrenergic receptor blockade may increase oxygen requirements by increasing left ventricular fiber length and end-diastolic pressure (preload).

The mechanisms involved in reducing mortality in patients with acute myocardial infarction are not fully understood.

**Pharmacodynamics**
Significant \(\beta\)-blocking effect (as measured by reduction of exercise heart rate) occurs within one hour after oral administration, and its duration is dose-related. For example, a 50% reduction of the maximum effect after single oral doses of 20, 50 and 100 mg occurred at 3.3, 5.0 and 6.4 hours, respectively, in normal subjects. After repeated oral dosages of 100 mg twice daily, a significant reduction in exercise systolic blood pressure was evident at 12 hours.

**Pharmacokinetic and pharmacodynamic relationship**
Following intravenous administration of metoprolol tartrate the half-life of the distribution phase is approximately 12 minutes; the urinary recovery of unchanged drug is approximately 10%. When the drug was infused over a 10-minute period, in normal volunteers, maximum \(\beta\)-blockade was achieved at approximately 20 minutes. Doses of 5 mg and 15 mg yielded a maximal reduction in exercise-induced heart rate of approximately 10% and 15%, respectively. The effect on exercise heart rate decreased linearly with time at the same rate for both doses, and disappeared at approximately 5 hours and 8 hours for the 5 mg and 15 mg doses, respectively.

Equivalent maximal \(\beta\)-blocking effect is achieved with oral and intravenous doses in the ratio of approximately 2.5:1.
There is a linear relationship between the log of plasma levels and reduction of exercise heart rate. However, antihypertensive activity does not appear to be related to plasma levels. Because of variable plasma levels attained with a given dose and lack of a consistent relationship of antihypertensive activity to dose, selection of proper dosage requires individual titration.

In several studies of patients with acute myocardial infarction, intravenous followed by oral administration of metoprolol tartrate caused a reduction in heart rate, systolic blood pressure, and cardiac output. Stroke volume, diastolic blood pressure, and pulmonary artery end-diastolic pressure remained unchanged.

The SR formulation produced lower peak metoprolol plasma concentrations than the regular tablets in studies with volunteers. Between 4 to 6 hours, both concentration curves were similar. During the 8 to 24 hour period concentrations were higher with the SR tablets.

**Pharmacokinetics**

The drug is available in racemic form and it exhibits stereo-specific pharmacokinetics.

**Absorption:** In humans, following oral administration of conventional tablet, metoprolol is rapidly and almost completely absorbed from the gastrointestinal tract. The drug is absorbed evenly throughout gastrointestinal tract. Plasma levels following oral administration, however, approximate 50% of levels following intravenous administration, indicating about 50% first-pass metabolism.

Inter-subject plasma levels achieved are highly variable after oral administration, although they show good reproducibility within each individual. Peak plasma concentrations are attained after approximately 1.5 to 2 hours with conventional metoprolol formulations, and after approximately 4-5 hours with prolonged-release formulations. Following repeated oral administration, the percentage of the dose systemically available is higher than after a single dose and also increases dose dependently. Only a small fraction of the drug (about 12%) is bound to human serum albumin.

**Distribution:** Metoprolol is rapidly and extensively distributed to the extra-vascular tissue. The mean volume of distribution is 3.2 to 5.6 L/kg. The apparent volume of distribution at steady-state (Vss) in extensive metabolizers (4.84 L/kg) is almost 2-fold higher that of poor metabolizers (2.83 L/kg). At therapeutic concentrations, approximately 12% of the active ingredient in metoprolol tartrate is bound to human serum proteins. Metoprolol crosses the placenta and is found in breast milk (see *Warning and Precautions – Nursing Women*).

**Biotransformation / Metabolism:** Metoprolol is not a significant P-glycoprotein substrate but is extensively metabolised by enzymes of the cytochrome P450 system in the liver. The oxidative metabolism of metoprolol is under genetic control with a major contribution of the polymorphic cytochrome P450 isoform 2D6 (CYP2D6), which causes inter-individual variability in pharmacokinetics and pharmacodynamics of metoprolol.
Indeed, the accumulation of metoprolol leads to high levels of the drug in plasma in poor metabolizers (PMs), which are associated with higher intensity of therapeutic effects, an increase in duration of action and an increase in the occurrence and severity of AEs as compared to extensive metabolizers (EMs).

**Metabolism & Dose-proportionality:** Metoprolol exhibits saturable pre-systemic metabolism leading to non-proportionate increase in exposure with increased dose. However, dose proportionate pharmacokinetics is expected with extended release formulations.

Food enhances the bioavailability of an oral dose of metoprolol by approximately 20 to 40%. Indeed, food intake affects the pharmacokinetics of metoprolol leading to increased exposure (AUC) and a higher maximum plasma concentration ($C_{\text{max}}$) (see Drug Interaction - Drug-Food Interactions).

In one clinical study with metoprolol immediate release formulation, it was found that $C_{\text{max}}$ and AUC were higher by about 32% and 38%, respectively, when administered after standard breakfast as compared to fasting condition. The study recommended that the drug should be administered with or immediately following meals to minimize the variations within an individual.

**Elimination:** Elimination is mainly by biotransformation in the liver, and the plasma half-life averages 3.5 hours (range: 1 [in EMs] to 9 hours [in PMs]). The total clearance rate of an intravenous dose is approximately 1L/min and the protein binding rate is approximately 10%. Less than 5% of an oral dose of metoprolol is recovered unchanged in the urine; the rest is excreted by the kidneys as metabolites that appear to have no clinical significance. Following single oral administration of 100 mg metoprolol the median clearance were 31, 168, and 367 L/h in poor metabolizers, extensive metabolizers, and ultrarapid metabolizers, respectively.

**Special Populations and Conditions**

**Elderly:** The elderly population show higher plasma concentrations of metoprolol (up to 28% AUC increase in elderly patients as compared to young healthy volunteers) as a combined result of a decreased elimination of metoprolol and the metabolite α-hydroxy- metoprolol and a decreased hepatic blood flow due to age-related physiological changes. In addition, time to reach peak concentration, $T_{\text{max}}$, was significantly longer in the elderly population. Hence, it is recommended to initiate therapy with lower doses in this group and safety monitoring may be recommended.

**Ethnic sensitivity:** The oxidative metabolism of metoprolol is under genetic control with a major contribution of the polymorphic cytochrome P450 isoform 2D6 (CYP2D6). There are marked ethnic differences in the prevalence of the poor metabolizers (PM) phenotype. Approximately 7% of Caucasians and less than 1% Orientals are PMs. CYP2D6 poor metabolizers exhibit 5-fold higher plasma concentrations of metoprolol than extensive metabolizers with normal CYP2D6 activity.
**Hepatic impairment:** Since the drug is primarily eliminated by hepatic metabolism, hepatic impairment impacts the pharmacokinetics of metoprolol. The elimination half-life of metoprolol is considerably prolonged, depending on severity (up to 7.2 h), in patients with liver impairment. Hence, dose adjustment and safety monitoring are advised in patients with mild to moderate hepatic impairment. Patients with severe hepatic impairment should be treated with caution, i.e. lower initial and maintenance doses as well as regular monitoring of hepatic function, as they are more sensitive to therapeutic effects/adverse effects of drugs.

**Renal impairment:** Pharmacokinetics of metoprolol in patient with renal impairment did not differ to a clinically significant degree from normal subjects. However, there is accumulation of one of its less active metabolite in patients with a creatinine clearance below 5 mL/min. Since the resulting metabolite accumulation has no significant effect on the β-blocking effects, metoprolol dosing does not need to be altered in patient with mild to moderate renal impairment. Caution is advised in the use of a beta-blocker in patients with severe renal impairment and safety monitoring is advised in these patients.

**Comparative Bioavailability-Apo-Metoprolol Tablets**

A randomized, single-dose, double-blinded, 2-way crossover comparative bioavailability study, conducted under fasting conditions, was performed on eighteen healthy male volunteers. The rate and extent of absorption of metoprolol was measured and compared following a single oral dose of Apo-Metoprolol or Betaloc 100 mg tablets. The results from measured data are summarized in the following table.

## Based on the least squares estimate.
† Lopresor SR ® is manufactured by Novartis Pharmaceuticals Canada Inc., and was purchased in Canada.

A randomized, single-dose, double-blinded, 2-way crossover comparative bioavailability study, conducted under fed conditions, was performed on fifteen healthy male volunteers. The rate and extent of absorption of metoprolol was measured and compared following a single oral dose of Apo-Metoprolol SR or Lopresor SR tablets 100 mg tablets. The results from measured data are summarized in the following table.

**STORAGE AND STABILITY**

APO-METOPROLOL/APO-METOPROLOL (Type L): Store at room temperature (15°C to 30°C) and protect from light.

APO-METOPROLOL SR: Store at room temperature between 15°C to 30°C.

**SPECIAL HANDLING INSTRUCTIONS**

Not Applicable

**DOSAGE FORMS, COMPOSITION AND PACKAGING**

*Composition*

APO-METOPROLOL 25 mg, 50 mg, 100 mg: In addition to metoprolol tartrate, each tablet contains the non-medicinal ingredients colloidal silicon dioxide, croscarmellose sodium, lactose monohydrate, magnesium stearate and microcrystalline cellulose.

APO-METOPROLOL (Type L) 50 mg: In addition to metoprolol tartrate, each tablet contains the following non-medicinal ingredients: colloidal silicon dioxide, croscarmellose sodium, lactose monohydrate, magnesium stearate and microcrystalline cellulose. It also contains carnauba wax, D & C Red # 30 Aluminum Lake 30%, hydroxypropyl methylcellulose, polyethylene glycol, sunset Yellow Aluminum Lake 40% and titanium dioxide.

APO-METOPROLOL (Type L) 100 mg: In addition to metoprolol tartrate, each tablet contains the following non-medicinal ingredients: croscarmellose sodium, colloidal silicon dioxide, lactose monohydrate, magnesium stearate and microcrystalline cellulose. It also contains carnauba wax, hydroxypropyl methylcellulose, Indigotine Aluminum Lake 12-14% (Blue #2) polydextrose, polyethylene glycol and titanium dioxide.
Composition: Prolonged-release Tablets

APO-METOPROLOL SR Tablets 100 mg & 200 mg: In addition to metoprolol tartrate, each prolonged-release tablet also contains the following non-medicinal ingredients; colloidal silicon dioxide, ferric oxide red (100 mg tablet only), ferric oxide yellow, hydroxypropyl methylcellulose, hydroxypropyl cellulose, magnesium stearate, methylcellulose, polyethylene glycol, stearic acid, and titanium dioxide.

APO-METOPROLOL 25 mg: Each white, oval, biconvex tablet, scored and engraved ‘ME ’over ‘25’ on one side and ‘APO’ on the other, contains 25 mg metoprolol tartrate. Available in bottles of 100, 500 and 1000 tablets.

APO-METOPROLOL 50 mg: Each white, round, biconvex, scored tablet engraved ‘APO’ over ‘M50’ on one side contains 50 mg metoprolol tartrate. Available in bottles of 100 and 1000 and in unit dose packages of 100 (10x10) tablets.

APO-METOPROLOL 100 mg: Each white, round, biconvex, scored tablet engraved ‘APO’ over ‘M100’ on one side contains 100 mg metoprolol tartrate. Available in bottles of 100 and 1000 and in unit dose packages of 100 (10x10) tablets.

APO-METOPROLOL (Type L) 50 mg: Each pink, capsule shaped, biconvex, scored, film coated tablet engraved ‘50’ on one side contains 50 mg metoprolol tartrate. Available in bottles of 100 and 1000 and in unit dose packages of 100 (10x10) tablets.

APO-METOPROLOL (Type L) 100 mg: Each blue, capsule shaped, biconvex, scored, film coated tablet engraved ‘100’ on one side contains 100 mg metoprolol tartrate. Available in bottles of 100 and 1000 and in unit dose packages of 100 (10x10) tablets.

APO-METOPROLOL SR 100 mg: Each orange-brown, round, biconvex, film-coated tablet engraved ‘APO’ on one side and ‘SR’ over ‘M100’ on the other side contains 100 mg metoprolol tartrate. Available in bottles of 100 tablets.

APO-METOPROLOL SR 200 mg: Each light yellow, round, biconvex, film-coated tablet engraved ‘APO’ on one side and ‘SR’ over ‘M200’ on the other side contains 200 mg metoprolol tartrate. Available in bottles of 100 tablets.
PART II: SCIENTIFIC INFORMATION

PHARMACEUTICAL INFORMATION

Drug Substance

Metoprolol tartrate

Chemical Name:
1. 2-Propanol, 1-[4-(2-methoxyethyl)phenoxy]-3-[(1-methylethyl)amino]-, (4), [R-(R*,R*)]-2,3-dihydroxybutanedioate) (2:1) (salt)
2. (±)-1-(Isopropylamino)-3-[p-(2-methoxyethyl) phenoxy]-2-propanol L-(+)-tartrate (2:1) (salt);
3. 1-Isopropylamino-3-[p-(2-methoxyethyl)-phenoxy]-2-propanol (2:1) dextro-tartrate salt.

Molecular Formula: C₃₄H₅₆N₂O₁₂

Molecular Weight: 685 g/mol

Structural Formula:

Physicochemical properties: Metoprolol is the tartrate salt of an organic base. It is a colourless, odorless, crystalline powder with a bitter taste. At 20°C it is 10% soluble in water. The pH of a 2% aqueous solution is 6.7.

DETAILED PHARMACOLOGY

Effect on the Cardiovascular System

Metoprolol produced dose-dependent reductions in heart rate and contractile force responses to sympathetic nerve stimulation in the anaesthetized cat. The ED₅₀ value for blockade of the chronotropic response to nerve stimulation was approximately 7 times less than that for isoproterenol stimulation. Metoprolol reduced the heart rate in conscious dogs at rest and during exercise. With the exception of PR interval prolongation, ECG complexes were not changed.

In anaesthetized cats, intravenous doses up to 2.0 mg/kg did not significantly influence the pressor response to intravenous epinephrine.
In anaesthetized cats, intravenously-administered metoprolol antagonized the hind limb vasodilating response to intra-arterial isoproterenol in much higher doses (ED$_{50}$ 5 mg/kg) than required to block the increase in chronotropic response (ED$_{50}$ 0.4 mg/kg) or increase in contractile force (ED$_{50}$ 0.2 mg/kg).

In 5 healthy volunteers, intravenously-administered 10 mg doses of metoprolol reduced exercise induced tachycardia by 13% and systolic blood pressure during exercise by 13%. The decrease in mean blood pressure after epinephrine was abolished by metoprolol, whereas the increase in systolic blood pressure was reduced by 50%; vascular resistance in the forearm was unchanged after metoprolol.

In healthy volunteers, intravenous metoprolol 0.15 mg/kg significantly lowered cardiac output by 1.3 litre/min. at rest, and 3.6 litre/min. during exercise. The mean decreases in heart rate were 9 and 16 beats/min. during rest and exercise, respectively. Right atrial pressure was significantly increased during rest and exercise. Oxygen consumption was not significantly influenced by drug administration. Significant increases in the calculated arteriovenous oxygen differences were observed (6 and 20 mL/litre at rest and during exercise, respectively).

Studies in reserpinized cats showed that metoprolol was devoid of β-receptor stimulating (intrinsic) activity. In cumulative doses up to 0.85 mg/kg, the drug did not significantly influence heart rate or contractile force.

A single oral dose of 40 mg of metoprolol administered to 17 anginal patients 90 minutes before testing, increased total work performed from 5994 to 8462 k.p.m. (40%). Times to onset of pain and appearance of ST depression were similarly increased from 11.8 to 16.9 minutes and 9.9 to 13.9 minutes respectively.

**Effects on Pulmonary Function**
The effects on specific airways resistance (S$_{Raw}$) of single oral doses of 100 mg of metoprolol were assessed in 6 healthy volunteers and in 12 patients with bronchial asthma. No bronchodilator was used. Metoprolol did not have a significant effect on S$_{Raw}$ in the normal subjects, but in the asthmatic patients, S$_{Raw}$ was significantly increased. Similar findings were observed with an 80 mg dose of propranolol.

In a controlled study, 17 patients with bronchial asthma received concomitantly a bronchodilator (terbutaline) with 50 or 100 mg b.i.d. of metoprolol. The FEV$_1$ values fell only in the high dose group, indicating some b2-blocking effect.

**Other Effects**
Metoprolol showed a negligible local anaesthetic effect on the isolated sciatic nerve of the frog and in the intracutaneous wheal test in guinea pigs. The cardiostimulant effects of ouabain, glucagon and theophylline were not affected by doses of 2 to 3 mg/kg in the anaesthetized cat. The same dosage of metoprolol was found to be devoid of anticholinergic, ganglionic blocking, antihistaminic and alpha-receptor blocking properties in cats.
Metoprolol inhibited the increase in plasma renin activity induced by furosemide.

The effects of metoprolol on isoproterenol-stimulated metabolic effects showed inhibition of the increase in liberation of glycerol, glucose, insulin, and free fatty acids.

The toxic symptoms in rats include: sedation, ataxia, piloerection, irritation, spasm, and lacrimation. Rats were unconscious before death, which occurred within 5-10 minutes after intravenous injection and 6 to 20 hours after oral administration.

In mice the most pronounced symptoms were: sedation, hypersensitivity, irritation, spasms, and ptosis. Convulsions were seen before death, which occurred within 5 minutes after intravenous injection. No symptoms of toxicity were detectable 24 hours after administration in surviving animals.

Teratology and Reproduction Studies

Rat: (Sprague-Dawley strain) Doses of 10, 50 and 200 mg/kg were administered orally to groups of 20 pregnant rats on days 6 to 15 of gestation. Treatment with metoprolol did not adversely affect any of the parameters studied.

Rabbit: (New Zealand White strain) Doses of 5, 12.5 and 25 mg/kg were administered orally to groups of 20 pregnant rabbits on days 6-18 of gestation. Parameters studied were not significantly affected, although litter size was lower and fetal loss higher in the high dose group. The incidence of fetal abnormality was unaffected by treatment.

Rat: (Sprague-Dawley strain) Doses of 10, 50 and 200 mg/kg were administered orally to groups of 50 rats from day 15 of gestation, through lactation to 21 days postpartum. Parameters studied in litter and parent animals were not adversely affected.

Rat: (Charles River CD strain) Doses of 50 and 500 mg/kg were administered orally to groups of 10 male and 20 female rats. Males were treated for 63 days prior to mating and during the mating period. The females were treated for 14 days prior to mating, during mating and throughout the gestation and lactation periods to 21 days postpartum, with an interim sacrifice at day 13 of gestation. The only significant finding in this study was a slight reduction of intrauterine growth in rats at 50 and 500 mg/kg/day and a higher frequency of stillbirths in the high dose group.

Carcinogenicity Studies

Metoprolol was administered to 3 groups of 60 male and 60 female Charles River Sprague-Dawley rats at dietary levels of 50, 200 and 800 mg/kg per day for 78 weeks. A fourth group received 2-AAF (positive control) and the fifth was the negative control group. The incidence of nodules and masses observed at necropsy were comparable between the treated and control groups. The only histopathological changes noted were an increased incidence of impaction of pulmonary alveoli by septal cells in the high and intermediate metoprolol-treated groups. The strain of rats was susceptible to the known carcinogen 2-AAF; a statistically higher incidence of neoplasms, primarily hepatomas, was present.

A similar study in Swiss albino mice at doses of 75, 150 and 750 mg/kg per day for 78 weeks showed that the tumors were distributed with equal frequency in the treated and control groups. The strain was susceptible to the known carcinogen.

This leaflet is part III of a three-part "Product Monograph" published when APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR was approved for sale in Canada and is designed specifically for Consumers. This leaflet is a summary and will not tell you everything about APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR. Contact your doctor or pharmacist if you have any questions about the drug.

This information applies to APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR. To facilitate reading, only APO-METOPROLOL is mentioned (unless the information for each product is different).

ABOUT THIS MEDICATION

What the medication is used for:
APO-METOPROLOL is used alone or in combination with another medicine for the following conditions:
- to treat high blood pressure
- to treat angina (chest pain triggered by exercise)
- to help to protect the heart after a heart attack (myocardial infarction)

What it does:
APO-METOPROLOL is a beta-blocker. It helps to control high blood pressure or other heart-related problems.

When it should not be used:
You should not be treated with APO-METOPROLOL if you:
- have non-treated tumor of the medulla of the adrenal glands (pheochromocytoma)
- have asthma or had history of difficulty breathing with wheezing or coughing
- have severe skin problems
- suffer from severe drop in blood pressure, dizziness, fast heartbeat, rapid and shallow breathing, cold clammy skin (signs of a heart disorder named cardiogenic shock).

What the medicinal ingredient is:
metoprolol tartrate.

What the nonmedicinal ingredients are:
APO-METOPROLOL 25 mg, 50 mg, 100 mg: In addition to metoprolol tartrate, each tablet contains the non-medicinal ingredients colloidal silicon dioxide, croscarmellose sodium, lactose monohydrate, magnesium stearate, and microcrystalline cellulose.

APO-METOPROLOL (Type L) 50 mg: In addition to metoprolol tartrate, each tablet contains the following non-medicinal ingredients: colloidal silicon dioxide, croscarmellose sodium, lactose monohydrate, magnesium stearate, and microcrystalline cellulose. It also contains carnauba wax, D & C Red # 30 Aluminum Lake 30%, hydroxypropyl methylcellulose, polyethylene glycol, Sunset Yellow Aluminum Lake 40% and titanium dioxide.

APO-METOPROLOL (Type L) 100 mg: In addition to metoprolol tartrate, each tablet contains the following non-medicinal ingredients: colloidal silicon dioxide, croscarmellose sodium, lactose monohydrate, magnesium stearate, and microcrystalline cellulose. It also contains carnauba wax, hydroxypropyl methylcellulose, Indigotine Aluminum Lake 12-14% (Blue #2), polydextrose, polyethylene glycol and titanium dioxide.

APO-METOPROLOL SR contain: colloidal silicon dioxide, ferric oxide red (100 mg tablet only), ferric oxide yellow hydroxypropyl cellulose, hydroxypropyl methylcellulose, magnesium stearate, methylcellulose, polyethylene glycol, stearic acid and titanium dioxide.

What dosage forms it comes in:
APO-METOPROLOL Tablets 25, 50 & 100 mg
APO-METOPROLOL (Type L) 50 & 100 mg
APO-METOPROLOL SR 100 & 200 mg

WARNINGS AND PRECAUTIONS

BEFORE you use APO-METOPROLOL talk to your doctor or pharmacist if you:
- have heart, liver or kidney disease
- have high or low levels of sugar in the blood (diabetes)

Before you use APO-METOPROLOL, talk to your doctor or pharmacist if you have any of these conditions:
- heart, liver or kidney disease
- high or low levels of sugar in the blood (diabetes)

If you do not know if you have any of these conditions, talk to your doctor or pharmacist before you use APO-METOPROLOL.
IMPORTANT: PLEASE READ

- are at risk for serious allergic reactions
- have chest pain when you are at rest
- have poor blood circulation in your limbs (for example, very cold, pale hands or feet, or pain in your leg muscles when you walk)
- have a tumor of the medulla or of the adrenal glands (pheochromocytoma), you would require an additional treatment to APO-METOPROLOL
- have allergy to or intolerance to lactose. This applies only to APO-METOPROLOL (25 mg, 50 mg, 100 mg) and APO-METOPROLOL (Type L) (50 mg, 100 mg)
- have an overactive thyroid gland
- have respiratory disease such as asthma, or sometimes get breathlessness and wheezing
- have a severe syndrome named oculomucocutaneous syndrome whose signs include severe conjunctivitis (red irritated and watery eye), skin rash and ear infection
- are pregnant, or intend to become pregnant. APO-METOPROLOL should not be used during pregnancy. Your doctor will discuss with you the potential risks of taking APO-METOPROLOL during pregnancy
- are breast feeding. If your doctor decides that you must continue to take APO-METOPROLOL you should stop breast- feeding as APO-METOPROLOL passes into breast milk
- are under 18 years old.

If you need to undergo an operation where an anesthetic is used, tell your anesthetic professional that you are taking APO-METOPROLOL.

Driving and using machines: If you experience dizziness, tiredness or blurred vision during your treatment with APO-METOPROLOL, do not drive, use machinery, or perform other tasks that need full attention until you know how you respond to APO-METOPROLOL. Drinking alcohol may increase tiredness.

INTERACTIONS WITH THIS MEDICATION

Tell your doctor or pharmacist if you are taking or have recently taken any other medicines, including herbal and non-prescription medicines. Some other medicines may interact with APO-METOPROLOL. These include:
- medicines used to treat high blood pressure,
- medicines used to treat chest pain (angina) (e.g. nitroglycerin),
- medicines used to treat irregular heartbeat (e.g. amiodarone, propafenone, quinidine, disopyramide,tocainide, procaainamide,ajmalineamiodarone, flecainide, digitalis glycosides such as digoxin, lidocaine)
- anaesthetics, medicines used during surgical operations,
- adrenaline or similar substances (sympathomimetics), which are found in some eye and nose drops, and in some cough medicines or remedies for the common cold (e.g. noradrenaline, isoprenaline, ephedrine, phenylephrine, phenylpropanolamine, and xanthine derivatives),
- insulin, or medicines used to treat high levels of sugar in the blood (diabetes),
- medicines used to relieve pain or inflammation (non-steroidal anti-inflammatory drugs such as COX-2 inhibitors),
- antibotics (e.g. rifampicin),
- antivirals (e.g. ritonavir),
- antihistamines used to treat hay fever (e.g. diphenhydramine),
- medicines used to treat malaria (e.g. hydroxychloroquine or quinine),
- antipsychotic medicines (e.g. thioridazine, chlorpromazine, fluphenazine, haloperidol),
- antidepressants (e.g. fluoxetine, paroxetine, fluvoxamine, sertraline, clomipramine, desipramine or bupropion),
- MOA Inhibitors and adrenergic neuron blockers (e.g. reserpine or guanethidine),
- antifungals (e.g. terbinafine),
- ergot alkaloids, used in the prevention and treatment of migraine headaches,
- dipyridamole, used to reduce the risk of blood clots, alcohol.
- fingolimod, a medicine used to treat multiple sclerosis

PROPER USE OF THIS MEDICATION

Usual dose:
Follow your doctor’s instructions carefully. Do not exceed the recommended dosage.

Your doctor will tell you exactly how many tablets of APO-METOPROLOL to take based on your individual requirements.

High Blood Pressure: the usual maintenance dose is 100 to 200 mg daily.

Angina: the usual maintenance dose is 200 mg daily.

To Protect the Heart After a Heart Attack: the usual maintenance dose is 100 mg twice daily.

In general, the daily dosage is in the following range: 100 to 200 mg daily, either once daily (in the morning), or divided into two separate doses (one in the morning and one in the evening).

Depending on how you respond to the treatment, your doctor may suggest a higher or lower dose.

APO-METOPROLOL SR tablets are intended for
maintenance dosing. Once your doctor has identified the correct dosage for you using the regular APO-METOPROLOL tablets, you may be switched to the APO-METOPROLOL SR tablets. APO-METOPROLOL SR tablets are convenient because you only take one pill a day. APO-METOPROLOL SR tablets should be taken in the morning.

APO-METOPROLOL / APO-METOPROLOL (Type L) / APO-METOPROLOL SR tablets should be swallowed whole without being chewed, preferably with or following a meal.

Do not change the dose or stop the treatment without talking to your doctor. If you stop taking APO-METOPROLOL suddenly, your condition may become worse. Your doctor may want you to reduce the dose gradually before stopping treatment altogether.

Overdose:

In case of drug overdose, contact a health care practitioner, hospital emergency department or regional Poison Control Centre immediately, even if there are no symptoms.

Some of the effects of an overdose of APO-METOPROLOL are: an abnormally slow heartbeat or an irregular heartbeat, very low blood pressure, breathlessness, difficulty breathing when lying down, swelling of the feet, loss of consciousness, blue discoloration of the lips, tongue, skin, seizures, nausea and vomiting, sudden and oppressive chest pain and death.

Missed Dose:
If you forget to take a dose of APO-METOPROLOL, take the missed dose as soon as you remember it. However, if it is almost time for the next dose, skip the missed dose and go back to your regular dosing schedule. Do not take a double dose.

SIDE EFFECTS AND WHAT TO DO ABOUT THEM

Like other medications, APO-METOPROLOL may cause some side effects. These side effects may be minor and temporary. However, some may be serious and need medical attention.

Side effects may include: sleep disturbance, fatigue and tiredness especially with activity, headache, dry mouth, nausea and vomiting, diarrhea or constipation and abdominal pain, numbness, a tingling sensation in the extremities signs of paresthesia, increased sensitivity of the skin to sun, sweating, hair loss, increased weight, and lower back pain.

Based on your health history, your doctor should take blood tests for as long as you are being treated with APO-METOPROLOL. They may monitor:
• blood sugar
• heart, liver, kidney and thyroid function
• how APO-METOPROLOL is affecting other medications that you are taking.

### SERIOUS SIDE EFFECTS, HOW OFTEN THEY HAPPEN AND WHAT TO DO ABOUT THEM

This is not a complete list of side effects. For any unexpected effects while taking APO-METOPROLOL contact your doctor or pharmacist.

**HOW TO STORE IT**

APO-METOPROLOL/APO-METOPROLOL (Type L): Store at room temperature (15°C to 30°C) and protect from light.

APO-METOPROLOL SR: Store at room temperature between 15°C to 30°C.

Keep all medicines out of the reach and sight of children. This medicine is prescribed for your specific medical problem and for your own use only. Do not give to other people.

Do not use outdated medicines. Discard them safely out of the reach of children or take them to your pharmacist who will dispose of them for you.
**Reporting Side Effects**

You can report any suspected side effects associated with the use of health products to Health Canada by:

- Visiting the Web page on Adverse Reaction Reporting ([https://www.canada.ca/en/health-canada/services/drugs-health-products/medeffect-canada/adverse-reaction-reporting.html](https://www.canada.ca/en/health-canada/services/drugs-health-products/medeffect-canada/adverse-reaction-reporting.html)) for information on how to report online, by mail or by fax; or
- Calling toll-free at 1-866-234-2345

*N NOTE: Contact your health professional if you need information about how to manage your side effects. The Canada Vigilance Program does not provide medical advice*
