PrLEVOFLOXACIN IN 5% DEXTROSE INJECTION

Levofloxacin

Sterile solution 5 mg / mL Antibacterial Agent

PART I: HEALTH PROFESSIONAL INFORMATION

SUMMARY PRODUCT INFORMATION

Route of Administration	Dosage Form / Strength	All Nonmedicinal Ingredients
Intravenous Infusion	Injection 5 mg / mL in 5% dextrose	Dextrose, and water for injection. Solutions of hydrochloric acid and/or sodium hydroxide may have been added to adjust the pH.

INDICATIONS AND CLINICAL USE

Levofloxacin in 5% Dextrose Injection is indicated for the treatment of adults with bacterial infections caused by susceptible strains of the designated microorganisms in the infections listed below.

Note: Since i.v. and oral formulations are interchangeable, i.v. administration is recommended only when it offers a route of administration advantageous to the patient (e.g., patient cannot tolerate oral dosage form).

To reduce the development of drug-resistant bacteria and maintain the effectiveness of Levofloxacin in 5% Dextrose Injection and other antibacterial drugs, Levofloxacin in 5% Dextrose Injection should be used only to treat infections that are proven or strongly suspected to be caused by susceptible bacteria. When culture and susceptibility information are available, they should be considered in selecting or modifying antibacterial therapy. In the absence of such data, local epidemiology and susceptibility patterns may contribute to the empiric selection of therapy.

Upper Respiratory Tract

Acute bacterial sinusitis (mild to moderate) due to *Streptococcus pneumoniae*, *Haemophilus influenzae*, or *Moraxella (Branhamella) catarrhalis*.

Restrict the use of Levofloxacin in 5% Dextrose Injection to settings where no other treatment options exist, and the clinical presentation meets the diagnostic criteria for acute bacterial sinusitis.¹

¹ Canadian clinical practice guidelines for acute and chronic rhinosinusitis. Desrosiers et al. *Allergy, Asthma* & *Clinical Immunology* 2011, 7:2.

Lower Respiratory Tract

Acute bacterial exacerbations of chronic bronchitis (mild to moderate) due to *Staphylococcus aureus*, *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Haemophilus parainfluenzae*, or *Moraxella (Branhamella) catarrhalis*. Levofloxacin in 5% Dextrose Injection should not be prescribed to patients with acute bacterial exacerbations of simple/uncomplicated chronic obstructive pulmonary disease (ie. patients who have chronic obstructive pulmonary disease without underlying risk factors).²

Community-acquired pneumonia (mild, moderate and severe infections) due to *Staphylococcus aureus*, *Streptococcus pneumoniae* (including penicillin-resistant strains), *Haemophilus influenzae*, *Haemophilus parainfluenzae*, *Klebsiella pneumoniae*, *Moraxella (Branhamella) catarrhalis*, *Chlamydia pneumoniae*, *Legionella pneumophila*, or *Mycoplasma pneumoniae* (see **DOSAGE AND ADMINISTRATION**, and *Product Monograph Part II:* CLINICAL **TRIALS**).

Nosocomial pneumonia due to methicillin-susceptible *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Serratia marcescens*, *Escherichia coli*, *Klebsiella pneumoniae*, *Haemophilus influenzae* or *Streptococcus pneumoniae*. Adjunctive therapy should be used as clinically indicated. Where *Pseudomonas aeruginosa* is a documented or presumptive pathogen, combination therapy with an anti-pseudomonal β -lactam is recommended.

Levofloxacin in 5% Dextrose Injection is not indicated for acute bronchitis.

Skin and Skin Structure

Uncomplicated skin and skin structure infections (mild to moderate) due to *Staphylococcus aureus* or *Streptococcus pyogenes*.

Complicated skin and skin structure infections (mild to moderate), excluding burns, due to *Enterococcus faecalis*, methicillin-sensitive *Staphylococcus aureus*, *Streptococcus pyogenes*, *Proteus mirabilis*, or *Streptococcus agalactiae*.

Urinary Tract

Complicated urinary tract infections (mild to moderate) due to *Enterococcus (Streptococcus)* faecalis, Enterobacter cloacae, Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, or Pseudomonas aeruginosa (see DOSAGE AND ADMINISTRATION and Product Monograph Part II: CLINICAL TRIALS).

Uncomplicated urinary tract infections (mild to moderate) due to *Escherichia coli, Klebsiella pneumoniae* or *Staphylococcus saprophyticus*.

Acute pyelonephritis (mild to moderate) caused by *Escherichia coli* (see **DOSAGE AND ADMINISTRATION** and *Product Monograph Part II*: CLINICAL TRIALS). Chronic bacterial prostatitis due to *Escherichia coli*, *Enterococcus faecalis*, or *Staphylococcus epidermidis*.

 ² Canadian Thoracic Society recommendations for management of chronic obstructive pulmonary disease –
 2008 update – highlights for primary care. O'Donnell et al. *Can Respir J* 2008; 15(Suppl A):1A-8A.

In cases of uncomplicated acute bacterial cystitis, limit the use of Levofloxacin in 5% Dextrose Injection to circumstances where no other treatment options are available. A urine culture should be obtained prior to treatment to ensure levofloxacin susceptibility.

Appropriate culture and susceptibility tests should be performed before treatment in order to isolate and identify the organisms causing the infection, and to determine their susceptibility to levofloxacin. Therapy with levofloxacin may be initiated before the results of these tests are known; once results become available, appropriate therapy should be continued.

As with other drugs in this class, some strains of Pseudomonas aeruginosa may develop resistance fairly rapidly during treatment with levofloxacin. Culture and susceptibility testing performed periodically during therapy, will reveal not only the therapeutic effect of the antimicrobial agent, but also the possible emergence of bacterial resistance.

<u>Geriatrics (≥ 65 years of age):</u>

Drug absorption appears to be unaffected by age. Dose adjustment based on age alone is not necessary (see WARNINGS AND PRECAUTIONS: <u>Special Populations</u> and ACTION AND CLINICAL PHARMACOLOGY: <u>Special Populations and Conditions</u>).

Pediatrics (<18 years of age):

Safety and effectiveness in children under 18 years of age have not been established (see **WARNINGS AND PRECAUTIONS:** <u>Special Populations</u>).

CONTRAINDICATIONS

Levofloxacin in 5% Dextrose Injection is contraindicated in persons with a history of hypersensitivity to levofloxacin, quinolone antimicrobial agents, or any other components of this product. For a complete listing, see the **DOSAGE FORMS, COMPOSITION AND PACKAGING** section of the Product Monograph.

Levofloxacin is also contraindicated in persons with a history of tendinitis or tendon rupture associated with the use of any member of the quinolone group of antimicrobial agents.

Serious Warnings and Precautions

- Fluoroquinolones, including Levofloxacin in 5% Dextrose Injection, have been associated with disabling and potentially persistent adverse reactions which to date include, but are not limited to: tendonitis, tendon rupture, peripheral neuropathy and neuropsychiatric effects.
- Levofloxacin has been shown to prolong the QT interval of the electrocardiogram in some patients (see WARNINGS AND PRECAUTIONS: <u>Cardiovascular</u>).
- Serious hypersensitivity and/or anaphylactic reactions have been reported in patients receiving quinolone therapy, including levofloxacin (see WARNINGS AND PRECAUTIONS: <u>Immune</u>).
- Fluoroquinolones, including levofloxacin, may exacerbate muscle weakness in persons with myasthenia gravis. Avoid levofloxacin in patients with a known history of myasthenia gravis (see WARNINGS AND PRECAUTIONS: <u>Musculoskeletal</u>).

<u>General</u>

The intravenous administration of levofloxacin increased the incidence and severity of osteochondrosis in immature rats and dogs. Other quinolones also produce similar erosions in the weight-bearing joints and other signs of arthropathy in immature animals of various species. Consequently, levofloxacin should not be used in pre-pubertal patients (see *Product Monograph Part II*: TOXICOLOGY).

Although levofloxacin is soluble, adequate hydration of patients receiving levofloxacin should be maintained to prevent the formation of a highly concentrated urine. Crystalluria has been observed rarely in patients receiving other quinolones, when associated with high doses and an alkaline urine. Although crystalluria was not observed in clinical trials with levofloxacin, patients are encouraged to remain adequately hydrated.

As with any antimicrobial drug, periodic assessment of organ system functions, including renal, hepatic, and hematopoietic, is advisable during prolonged therapy (see **ADVERSE REACTIONS**).

I.V. Administration

Because rapid or bolus intravenous injection may result in hypotension, LEVOFLOXACIN INJECTION SHOULD ONLY BE ADMINISTERED BY SLOW INTRAVENOUS INFUSION OVER A PERIOD OF 60 MINUTES FOR A 250 MG OR A 500 MG DOSE, AND 90 MINUTES FOR A 750 MG DOSE (see **DOSAGE AND ADMINISTRATION**).

Use of levofloxacin with other drugs may lead to drug-drug interactions (see DRUG INTERACTIONS: Drug-Drug Interactions).

Sexually Transmitted Diseases

Levofloxacin is not indicated for the treatment of syphilis or gonorrhea. Levofloxacin is not effective in the treatment of syphilis. Antimicrobial agents used in high doses for short periods of time to treat gonorrhea may mask or delay the symptoms of incubating syphilis. All patients with gonorrhea should have a serologic test for syphilis at the time of diagnosis. Patients treated with

antimicrobial agents with limited or no activity against *Treponema pallidum* should have a follow-up serologic test for syphilis after 3 months.

Blood Glucose Disturbances

Fluoroquinolones, including levofloxacin have been associated with disturbances of blood glucose, including symptomatic hyperglycemia and hypoglycemia, usually in diabetic patients receiving concomitant treatment with an oral hypoglycemic agent (e.g., glyburide) or with insulin. In these patients, careful monitoring of blood glucose is recommended. SEVERE CASES OF HYPOGLYCEMIA RESULTING IN COMA OR DEATH HAVE BEEN REPORTED. If a hypoglycemic reaction occurs, discontinue Levofloxacin in 5% Dextrose Injection immediately and initiate appropriate therapy.

Hypoglycemic coma has been observed in diabetic patients with the use of levofloxacin. Fatal outcomes have been reported. All cases of hypoglycemic coma had multiple compounding factors; a temporal relationship with the use of levofloxacin was identified (onset of altered consciousness occurred within 3 days in most cases). Caution should be exercised when using levofloxacin in diabetic patients taking concomitant treatment with an oral hypoglycemic agent and/or insulin, especially those who are elderly or who have renal impairment (see WARNINGS AND PRECAUTIONS: Renal and DRUG INTERACTIONS: <u>Drug-Drug Interactions</u>, Antidiabetic Agents).

<u>Cardiovascular</u>

Aortic Aneurysm and Aortic Dissection

Epidemiologic studies report an increased risk of aortic aneurysm and dissection after intake of fluoroquinolones, particularly in the older population.

Therefore, fluoroquinolones should only be used after careful benefit-risk assessment and after consideration of other therapeutic options in patients with positive family history of aneurysm disease, or in patients diagnosed with pre-existing aortic aneurysm and/or aortic dissection, or in presence of other risk factors for aortic aneurysm and dissection (e.g., Marfan syndrome, vascular Ehlers-Danlos syndrome, Takayasu arteritis, giant cell arteritis, Behcet's disease, hypertension, atherosclerosis).

In case of sudden severe abdominal, chest or back pain, patients should be advised to immediately consult a physician in an emergency department.

QT Prolongation

Some quinolones, including levofloxacin, have been associated with prolongation of the QT interval on the electrocardiogram and infrequent cases of arrhythmia. During post-marketing surveillance, very rare cases of torsades de pointes have been reported in patients taking levofloxacin. These reports generally involved patients with concurrent medical conditions or concomitant medications that may have been contributory. The risk of arrhythmias may be reduced by avoiding concurrent use with other drugs that prolong the QT interval including macrolide antibiotics, antipsychotics, tricyclic antidepressants, Class IA (e.g., quinidine, procainamide) or Class III (e.g., amiodarone, sotalol) antiarrhythmic agents, and cisapride. In addition, use of levofloxacin in the presence of risk factors for torsades de pointes such as hypokalemia, significant bradycardia, cardiomyopathy, patients with myocardial ischemia, and

<u>Central Nervous System Effects</u> Psychiatric Adverse Reactions

Fluoroquinolones, including levofloxacin, have been associated with an increased risk of psychiatric adverse reactions, including: toxic psychoses, hallucinations, or paranoia; depression, or suicidal thoughts; anxiety, agitation, restlessness, or nervousness; confusion, delirium, disorientation, or disturbances in attention; insomnia or nightmares; and memory impairment. Cases of attempted or completed suicide have been reported, especially in patients with a medical history of depression, or an underlying risk factor for depression. These reactions may occur following the first dose. If these reactions occur in patients receiving Levofloxacin in 5% Dextrose Injection, discontinue Levofloxacin in 5% Dextrose Injection and institute appropriate measures.

Central Nervous System Adverse Reactions

Fluoroquinolones, including levofloxacin, have been associated with an increased risk of seizures (convulsions), increased intracranial pressure (including pseudotumor cerebri), tremors, and light-headedness. As with other fluoroquinolones, levofloxacin should be used with caution in patients with a known or suspected central nervous system (CNS) disorder that may predispose them to seizures or lower the seizure threshold (e.g., severe cerebral arteriosclerosis, epilepsy) or in the presence of other risk factors that may predispose them to seizures or lower the seizure threshold (e.g., certain drug therapy, renal dysfunction). If these reactions occur in patients receiving Levofloxacin in 5% Dextrose Injection, discontinue Levofloxacin in 5% Dextrose Injection immediately and institute appropriate measures.

Gastrointestinal

Clostridium difficile-associated disease

Clostridium difficile-associated disease (CDAD) has been reported with use of many antibacterial agents, including levofloxacin. CDAD may range in severity from mild diarrhea to fatal colitis. It is important to consider this diagnosis in patients who present with diarrhea or symptoms of colitis, pseudomembranous colitis, toxic megacolon, or perforation of the colon subsequent to the administration of any antibacterial agent. CDAD has been reported to occur over 2 months after the administration of antibacterial agents.

Treatment with antibacterial agents may alter the normal flora of the colon and may permit overgrowth of *Clostridium difficile*. *C. difficile* produces toxins A and B, which contribute to the development of CDAD. CDAD may cause significant morbidity and mortality. CDAD can be refractory to antimicrobial therapy.

If the diagnosis of CDAD is suspected or confirmed, appropriate therapeutic measures should be initiated. Mild cases of CDAD usually respond to discontinuation of antibacterial agents not directed against *Clostridium difficile*. In moderate to severe cases, consideration should be given to management with fluids and electrolytes, protein supplementation, and treatment with an antibacterial agent clinically effective against *Clostridium difficile*. Surgical evaluation should be instituted as clinically indicated since surgical intervention may be required in certain severe cases (see **ADVERSE REACTIONS**).

<u>Hepatic</u>

Very rare post-marketing reports of severe hepatotoxicity (including acute hepatitis and fatal events) have been received for patients treated with levofloxacin. No evidence of serious drug-associated hepatotoxicity was detected in clinical trials of over 7,000 patients. Severe hepatotoxicity generally occurred within 14 days of initiation of therapy and most cases occurred within 6 days. Most cases of severe hepatotoxicity were not associated with hypersensitivity. The majority of fatal hepatotoxicity reports occurred in patients 65 years of age or older and most were not associated with hypersensitivity. Levofloxacin should be discontinued immediately if the patient develops signs and symptoms of hepatitis (see ADVERSE REACTIONS: <u>Post-Market Adverse Drug Reactions</u>).

Immune

Hypersensitivity

Serious and occasionally fatal hypersensitivity and/or anaphylactic reactions have been reported in patients receiving therapy with quinolones, including levofloxacin. These reactions often occur following the first dose. Some reactions have been accompanied by cardiovascular collapse, hypotension/shock, seizure, loss of consciousness, tingling, angioedema (including tongue, laryngeal, throat or facial edema/swelling), airway obstruction (including bronchospasm, shortness of breath, and acute respiratory distress), dyspnea, urticaria, itching, and other serious skin reactions. Levofloxacin should be discontinued immediately at the first appearance of a skin rash or any other sign of hypersensitivity. Serious acute hypersensitivity reactions may require treatment with epinephrine and other resuscitative measures, including oxygen, intravenous fluids, antihistamines, corticosteroids, pressor, amines and airway management, as clinically indicated (see **ADVERSE REACTIONS**).

Serious and sometimes fatal events, some due to hypersensitivity and some due to uncertain etiology, have rarely been reported in patients receiving therapy with quinolones, including levofloxacin. These events may be severe, and generally occur following the administration of multiple doses. Clinical manifestations may include one or more of the following: fever; rash or severe dermatologic reactions (e.g., toxic epidermal necrolysis, Stevens-Johnson syndrome); vasculitis; arthralgia; myalgia; serum sickness; allergic pneumonitis; interstitial nephritis; acute renal insufficiency or failure; hepatitis, including acute hepatitis; jaundice; acute hepatic necrosis or failure; anemia, including hemolytic and aplastic; thrombocytopenia, including thrombotic thrombocytopenic purpura; leukopenia; agranulocytosis; pancytopenia; and/or other hematologic abnormalities. The administration of levofloxacin should be discontinued immediately, at the first appearance of a skin rash or any other sign of hypersensitivity, and supportive measures instituted (see **ADVERSE REACTIONS**).

<u>Musculoskeletal</u>

Tendinitis

Rupture of the shoulder, hand and Achilles tendons that required surgical repair or resulted in prolonged disability have been reported in patients receiving quinolones, including Levofloxacin. Levofloxacin should be discontinued if the patient experiences pain, inflammation or rupture of a tendon. Patients should rest and refrain from exercise until the diagnosis of tendinitis or tendon rupture has been confidently excluded. The risk of developing fluoroquinolone-associated tendinitis and tendon rupture is further increased in older patients usually over 60 years of age, in patients taking corticosteroid drugs, and in patients with kidney,

heart or lung transplants. Factors, in addition to age and corticosteroid use, that may independently increase the risk of tendon rupture include strenuous physical activity, renal failure, and previous tendon disorders such as rheumatoid arthritis. Tendinitis and tendon rupture have also occurred in patients taking fluoroquinolones who do not have the above risk factors. Tendon rupture can occur during or after completion of therapy; cases occurring up to several months after completion of therapy have been reported. Levofloxacin should be discontinued if the patient experiences pain, swelling, inflammation or rupture of a tendon. Patients should be advised to rest at the first sign of tendinitis or tendon rupture, and to contact their healthcare provider regarding changing to a non-quinolone antimicrobial drug (see **ADVERSE REACTIONS**).

Levofloxacin should not be used in patients with a history of tendon disease/disorder related to previous quinolone treatment (see **CONTRAINDICATIONS**).

Myasthenia Gravis

Fluoroquinolones have neuromuscular blocking activity and may exacerbate muscle weakness in persons with myasthenia gravis. Post-marketing serious adverse events, including deaths and requirement for ventilatory support, have been associated with fluoroquinolone use (including Levofloxacin) in persons with myasthenia gravis. Avoid Levofloxacin in patients with a known history of myasthenia gravis (see **ADVERSE REACTIONS:** <u>Post-Market Adverse Drug</u> <u>Reactions</u>).

Neurologic

Peripheral Neuropathy

Rare cases of sensory or sensorimotor axonal polyneuropathy affecting small and/or large axons resulting in paresthesias, hypoesthesias, dysesthesias and weakness have been reported in patients receiving quinolones, including levofloxacin. Symptoms may occur soon after initiation of treatment and may be irreversible. Levofloxacin should be discontinued immediately if the patient experiences symptoms of neuropathy including pain, burning, tingling, numbness, and/or weakness or other alterations of sensation including light touch, pain, temperature, position sense, and vibratory sensation in order to prevent the development of an irreversible condition.

Renal

Safety and efficacy of levofloxacin in patients with impaired renal function (creatinine clearance ≤ 80 mL/min) have not been studied. Since levofloxacin is known to be substantially excreted by the kidney, the risk of toxic reactions to this drug may be greater in patients with impaired renal function. The potential effects of levofloxacin associated with possible increased serum/tissue levels in renal impaired patients, such as effect on QTc interval, have not been studied. Adjustment of the dosage regimen may be necessary to avoid the accumulation of levofloxacin due to decreased clearance. Careful clinical observation and appropriate laboratory studies should be performed prior to and during therapy, since elimination of levofloxacin may be reduced. Because elderly patients are more likely to have decreased renal function, care should be taken in dose selection, and it may be useful to monitor renal function. Administer levofloxacin with caution in the presence of renal insufficiency (see DOSAGE AND ADMINISTRATION: <u>Recommended Dose and Dosage Adjustment</u>, <u>Patients with Impaired Renal Function</u> and <u>Product Monograph Part II</u>: DETAILED PHARMACOLOGY, <u>Factors Influencing the Pharmacokinetics</u>, <u>Special Populations</u>, <u>Renal Insufficiency</u>).

<u>Skin</u> Phototoxicity

Moderate to severe phototoxicity reactions have been observed in patients exposed to direct sunlight or ultraviolet (UV) light while receiving drugs in this class. Excessive exposure to sunlight or UV light should be avoided. However, in clinical trials with levofloxacin, phototoxicity has been observed in less than 0.1% of patients. Therapy should be discontinued if phototoxicity (e.g., skin eruption) occurs.

Special Populations

The safety and efficacy of Levofloxacin in 5% Dextrose Injection in children, adolescents (under the age of 18 years), pregnant women, and nursing mothers have not been established.

Pregnant Women: There are no adequate and well-controlled studies in pregnant women. Levofloxacin should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus (see *Product Monograph Part II*: TOXICOLOGY).

Nursing Women: Levofloxacin has not been measured in human milk. Based upon data from ofloxacin, it can be presumed that levofloxacin can be excreted in human milk. Because of the potential for serious adverse reactions from levofloxacin in nursing infants, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother (see *Product Monograph Part II*: TOXICOLOGY).

Pediatrics (<18 years of age): Levofloxacin is not indicated for the treatment of patients younger than 18 years of age. Quinolones, including levofloxacin, cause arthropathy in juvenile animals of several species (see *Product Monograph Part II*: TOXICOLOGY). The incidence of protocol-defined musculoskeletal disorders in a prospective long-term surveillance study was higher in children treated for approximately 10 days with levofloxacin than in children treated with non-fluoroquinolone antibiotics for approximately 10 days (see ADVERSE REACTIONS).

Geriatrics (\geq 65 years of age): The pharmacokinetic properties of levofloxacin in younger adults and elderly adults do not differ significantly when creatinine clearance is taken into consideration. However, since the drug is known to be substantially excreted by the kidney, the risk of toxic reactions to this drug may be greater in patients with impaired renal function. Because elderly patients are more likely to have decreased renal function, care should be taken in dose selection. It may also be useful to monitor renal function.

Elderly patients may be more susceptible to drug-associated effects on the QT interval (see **WARNINGS AND PRECAUTIONS:** <u>Cardiovascular</u>).

Geriatric patients are at increased risk for developing severe tendon disorders including tendon rupture when being treated with a fluoroquinolone such as Levofloxacin. This risk is further increased in patients receiving concomitant corticosteroid therapy (see WARNINGS AND PRECAUTIONS: <u>Musculoskeletal</u>).

Severe and sometimes fatal cases of hepatotoxicity have been reported post-marketing in

association with Levofloxacin. The majority of fatal hepatotoxicity reports occurred in patients 65 years of age or older and most were not associated with hypersensitivity (see WARNINGS AND PRECAUTIONS: <u>Hepatic</u>).

Effects on Ability to Drive and Use Machines

Neurologic adverse effects such as dizziness and lightheadedness may occur. Therefore, patients should know how they react to levofloxacin before operating an automobile or machinery or engaging in other activities requiring mental alertness and coordination.

Superinfection

The use of levofloxacin may result in overgrowth of non-susceptible organisms. If superinfection occurs during therapy, appropriate measures should be taken.

Susceptibility/Resistance

Development of Drug Resistant Bacteria

Prescribing Levofloxacin in 5% Dextrose Injection in the absence of a proven or strongly suspected bacterial infection is unlikely to provide benefit to the patient and risks the development of drug-resistant bacteria.

Methicillin-resistant *Staphylococcus aureus* (MRSA) is very likely to possess co-resistance to fluoroquinolones, including levofloxacin. Therefore, Levofloxacin in 5% Dextrose Injection is not recommended for the treatment of known or suspected MRSA infections unless laboratory results have confirmed susceptibility of the organism to levofloxacin. In this case Levofloxacin in 5% Dextrose Injection can be used when commonly recommended antibacterial agents for the treatment of MRSA-infections are considered inappropriate.

Resistance of *Escherichia coli*, the most common pathogen involved in urinary tract infections, to fluoroquinolones varies. Prescribers are advised to take into account the local prevalence of resistance in *E. coli* to fluoroquinolones.

ADVERSE REACTIONS

Adverse Drug Reaction Overview

In North American Phase III clinical trials involving 7537 subjects, the incidence of treatmentemergent adverse events in patients treated with levofloxacin was comparable to comparators. The majority of adverse events were considered to be mild to moderate, with 5.6% of patients considered to have severe adverse events. Among patients receiving multiple-dose therapy, 4.2% discontinued therapy with levofloxacin due to adverse experiences. The incidence of drugrelated adverse reactions was 6.7%.

In clinical trials, the most frequently reported adverse drug reactions occurring in > 3% of the study population were nausea, headache, diarrhea, insomnia, dizziness and constipation.

Serious and otherwise important adverse drug reactions are discussed in greater detail in other sections (see **WARNINGS AND PRECAUTIONS**).

<u>Clinical Trial Adverse Drug Reactions</u>

Because clinical trials are conducted under very specific conditions the adverse reaction rates observed in the clinical trials may not reflect the rates observed in practice and should not be compared to the rates in the clinical trials of another drug. Adverse drug reaction information from clinical trials is useful for identifying drug-related adverse events and for approximating rates.

The data described below reflect exposure to levofloxacin in 7537 patients in 29 pooled Phase III clinical trials. The population studied had a mean age of 49.6 years (74.2% of the population was < 65 years), 50.1% were male, 71.0% were Caucasian and 18.8% were Black. Patients were treated with levofloxacin for a wide variety of infectious diseases (see INDICATIONS AND CLINICAL USE). Treatment duration was usually 3-14 days, the mean number of days on therapy was 9.6 days and the mean number of doses was 10.2. Patients received levofloxacin doses of 750 mg once daily, 250 mg once daily, or 500 mg once or twice daily. The overall incidence, type and distribution of adverse reactions were similar in patients receiving levofloxacin doses of 750 mg once daily, 250 mg once daily, and 500 mg once or twice daily.

Adverse reactions (characterized as likely related to drug-therapy) occurring in $\geq 1\%$ of levofloxacin-treated patients are shown in Table 1.1 below.

System/Organ Class	Adverse Reaction	% (N=7537)
Infections and Infestations	moniliasis	1
Psychiatric Disorders	insomnia	4 ^a
Nervous System Disorders	headache	6
	dizziness	3
Respiratory, Thoracic and Mediastinal	dyspnea	1

Table 1.1: Common (≥1%) Adverse Reactions Reported in Clinical Trials with levofloxacin

Less Common Clinical Trial Adverse Drug Reactions (<1%)

Less common adverse reactions occurring in 0.1 to <1% of levofloxacin-treated patients are shown in Table 1.2 below.

System/Organ Class	Adverse Reaction	
Blood and Lymphatic System	anemia, thrombocytopenia, granulocytopenia	
Cardiac Disorders	cardiac arrest, palpitation, ventricular tachycardia, ventricular	
	arrhythmia	
Gastrointestinal Disorders	gastritis, stomatitis, pancreatitis, oesophagitis, gastroenteritis,	
	glossitis, pseudomembraneous/ C.difficile colitis	
Hepatobiliary Disorders	abnormal hepatic function, increased hepatic enzymes, increased	
	alkaline phosphatase	
Immune System Disorders	allergic reaction	
Infections and Infestations	genital moniliasis	
Metabolism and Nutrition	hyperglycemia, hypoglycemia, hyperkalemia	
Musculoskeletal and Connective Tissue	tendinitis, arthralgia, myalgia, skeletal pain	
Disorders		
Nervous System Disorders	tremor, convulsions, parasthesia, vertigo, hypertonia,	
	hyperkinesias, abnormal gait, somnolence ^a , syncope	
Psychiatric Disorders	anxiety, agitation, confusion, depression, hallucination,	
	nightmare ^a , sleep disorder ^a , anorexia, abnormal dreaming ^a	
Renal and Urinary Disorders	abnormal renal function, acute renal failure	
Respiratory, Thoracic and Mediastinal	epistaxis	
Disorders		
Skin and Subcutaneous Tissue	urticaria	
Disorders		
Vascular Disorders	phlebitis	

 Table 1.2: Less Common (0.1 to 1%) Adverse Reactions Reported in Clinical Trials with levofloxacin

Rare (<0.1%) adverse reactions from Phase III studies include dyspnea and rash maculo-papular.

In clinical trials using multiple-dose therapy, ophthalmologic abnormalities, including cataracts and multiple punctate lenticular opacities, have been noted in patients undergoing treatment with other quinolones. The relationship of the drugs to these events is not presently established.

Crystalluria and cylindruria have been reported with other quinolones.

Abnormal Hematologic and Clinical Chemistry Findings

Laboratory abnormalities seen in > 2% of patients receiving multiple doses of levofloxacin: decreased glucose 2.1%

It is not known whether this abnormality was caused by the drug or the underlying condition being treated.

Pediatric Data

 $^{a}N = 7274$

In a group of 1534 pediatric patients (6 months to 16 years of age) treated with levofloxacin for respiratory infections, children 6 months to 5 years of age received 10 mg/kg of levofloxacin twice a day for approximately 10 days and children greater than 5 years of age received 10 mg/kg to a maximum of 500 mg of levofloxacin once a day for approximately 10 days. The adverse reaction profile was similar to that reported in adult patients. Vomiting and diarrhea were reported more frequently in children than reported in adults. However, the frequency of vomiting and diarrhea was similar in levofloxacin-treated and non-fluoroquinolone antibiotic

comparator-treated children.

A subset of 1340 of these children treated with levofloxacin for approximately 10 days was enrolled in a prospective, long-term, surveillance study to assess the incidence of protocoldefined musculoskeletal disorders (arthralgia, arthritis, tendonopathy, gait abnormality) during 60 days and 1 year following the first dose of levofloxacin.

During the 60-day period following the first dose, the incidence of protocol-defined musculoskeletal disorders was greater in levofloxacin-treated children than in non-fluoroquinolone antibiotic comparator-treated children (2.1% vs. 0.9%, respectively [p=0.038]). In 22/28 (78%) of these children, reported disorders were characterized as arthralgia. A similar observation was made during the one-year period, with a greater incidence of protocol-defined musculoskeletal disorders in levofloxacin-treated children than in non-fluoroquinolone antibiotic comparator-treated children (3.4% vs. 1.8%, respectively [p=0.025]). The majority of these disorders occurring in children treated with levofloxacin were mild and resolved within 7 days. Disorders were moderate in 8 children and mild in 35 (76%) children.

Post-Market Adverse Drug Reactions

Table 1.3 lists adverse reactions that have been identified during post-approval use of levofloxacin. Because these reactions are reported voluntarily from a population of uncertain size, reliably estimating their frequency or establishing a causal relationship to drug exposure is not always possible.

System Organ Class	Adverse Reaction	
Blood and Lymphatic System Disorders	pancytopenia, aplastic anemia, leucopenia, hemolytic anemia,	
Disorders	eosinophilia, thrombocytopenia including thrombotic thrombocytopenic purpura, agranulocytosis	
Cardiac Disorders	isolated reports of torsade de pointes, electrocardiogram QT prolonged, tachycardia	
Eye Disorders	uveitis, vision disturbance (including diplopia), visual acuity reduced, vision blurred, scotoma	
Ear and Labyrinth Disorders	hypoacusis, tinnitus	
General Disorders and	multi-organ failure, pyrexia, rash	
Administration Site Conditions		
Hepatobiliary Disorders	hepatic failure (including fatal cases), hepatitis, jaundice, hepatic necrosis	
Immune System Disorders	hypersensitivity reactions, sometimes fatal including: anaphylactic/anaphylactoid reactions, anaphylactic shock, angioneurotic edema, serum sickness	
Investigations	prothrombin time prolonged, international normalized ratio (INR) prolonged, muscle enzymes increased (CPK)	
Musculoskeletal and Connective Tissue Disorders	tendon rupture, muscle injury (including rupture), rhabdomyolysis, myositis, myalgia	
Nervous System Disorders	anosmia, ageusia, parosmia, dysgeusia, peripheral neuropathy (may be irreversible), isolated reports of encephalopathy, abnormal EEG, dysphonia, exacerbation of myasthenia gravis, amnesia, pseudotumor	
Psychiatric Disorders	psychosis, paranoia, isolated reports of suicide attempt and suicidal ideation	
Renal and Urinary Disorders	interstitial nephritis, nephrosis, glomerulonephritis	

Table 1.3: Post-marketing Reports of Adverse Drug Reactions

Respiratory, Thoracic and Mediastinal Disorders	isolated reports of allergic pneumonitis, interstitial pneumonia, laryngeal edema, apnea	
Disorders	bullous eruptions to include: Stevens-Johnson Syndrome, toxic epidermal necrolysis, erythema multiforme, photosensitivity/phototoxicity reaction, leukocytoclastic vasculitis	
Vascular Disorders	vasodilation, vasculitis, DIC	

DRUG INTERACTIONS

Overview

Levofloxacin undergoes limited metabolism in humans and is primarily excreted as unchanged drug in the urine. The P450 system is not involved in the levofloxacin metabolism, and is not affected by levofloxacin. Levofloxacin is unlikely to alter the pharmacokinetics of drugs metabolized by these enzymes. Disturbances of blood glucose have been reported in patients treated concomitantly with levofloxacin and an antidiabetic agent. Therefore, careful monitoring of blood glucose is recommended when these agents, including levofloxacin, are co-administered.

As with all other quinolones, iron and antacids significantly reduced bioavailability of levofloxacin. Concurrent administration of oral levofloxacin with antacids containing magnesium, or aluminium, as well as sucralfate, metal cations such as iron, and multivitamin preparations with zinc may interfere with the gastrointestinal absorption of levofloxacin, resulting in systemic levels considerably lower than desired. These agents should be taken at least two hours before or two hours after oral levofloxacin administration. **Drug-Drug Interactions**

Table 1.4: Established or Potential Drug-Drug Interactions

Proper name	Ref	Effect	Clinical comment
Antidiabetic Agents	C	Disturbances of blood glucose, including hyperglycemia and hypoglycemia, have been reported in patients treated concomitantly with levofloxacin and an antidiabetic agent. Some of these cases were serious including hypoglycemic coma.	Careful monitoring of blood glucose is recommended when these agents, including levofloxacin, are co- administered.

Proper name	Ref	Effect	Clinical comment
Cyclosporine	СТ	No significant effect of levofloxacin on the peak plasma concentrations, AUC, and other disposition parameters for cyclosporine was detected in a clinical study involving healthy volunteers. However, elevated serum levels of cyclosporine have been reported in the patient population when co-administered with some other quinolones. Levofloxacin C _{max} and k _e were slightly lower, while T _{max} and t ¹ / ₂ were slightly longer in the presence of cyclosporine, than those observed in other studies without concomitant medication. The differences, however, are not considered to be clinically significant.	No dosage adjustment is required for levofloxacin or cyclosporine when administered concomitantly.
Digoxin	СТ	No significant effect of levofloxacin on the peak plasma concentrations, AUC, and, other disposition parameters for digoxin was detected in a clinical study involving healthy volunteers. Levofloxacin absorption and disposition kinetics were similar in the presence or absence of digoxin.	No dosage adjustment for levofloxacin or digoxin is required when administered concomitantly. Digoxin levels should be closely monitored in patients receiving concomitant therapy with digoxin.
Non-Steroidal Anti- Inflammatory Drugs (NSAIDs)	Т	Although not observed with levofloxacin in clinical trials, some quinolones have been reported to have proconvulsant activity that is exacerbated with concominant use of NSAIDs.	The concomitant administration of a non-steroidal anti-inflammatory drug with a quinolone, including levofloxacin, may increase the risk of CNS stimulation and convulsive seizures (see WARNINGS AND PRECAUTIONS: <u>Neurologic</u> and <i>Product Monograph Part II</i> , DETAILED PHARMACOLOGY: <u>Animal Pharmacology</u>).
Probenecid and Cimetidine	СТ	No significant effect of probenecid or cimetidine on the rate and extent of levofloxacin absorption was observed in a clinical study involving healthy volunteers. The AUC and $t^{1/2}$ of levofloxacin were 27-38% and 30% higher, respectively, while CL/F and Cl _r were 21-35% lower during concomitant treatment with probenecid or cimetidine compared to levofloxacin alone.	No dosage adjustment for levofloxacin is required when administered concomitantly with probenecid or cimetidine <i>except</i> dosage adjustment for levofloxacin may be required based on the renal function of the patient.

Proper name	Ref	Effect	Clinical comment	
Theophylline	CT/T	No significant effect of levofloxacin on the plasma concentrations, AUC, and other disposition parameters for theophylline was detected in a clinical study involving 14 healthy volunteers. Similarly, no apparent effect of theophylline on levofloxacin absorption and disposition was observed. However, concomitant administration of other quinolones with theophylline has resulted in prolonged elimination, elevated serum theophylline levels, and a subsequent increase in the risk of theophylline-related adverse reactions in the patient population.	Theophylline levels should be closely monitored, and theophylline dosage adjustments made if appropriate, when levofloxacin is co- administered. Adverse reactions, including seizures, may occur with or without an elevation in serum theophylline level (see WARNINGS AND PRECAUTIONS).	
Warfarin	Т	Certain quinolones, including levofloxacin, may enhance the effects of oral anticoagulant warfarin or its derivatives.	When these products are administered concomitantly, prothrombin time, International Normalized Ratio (INR), or other suitable coagulation tests should be monitored closely, especially in the elderly patients.	
Zidovudine	СТ	Levofloxacin absorption and disposition in HIV-infected subjects, with or without concomitant zidovudine treatment, were similar. The effect of levofloxacin on zidovudine pharmacokinetics has not been studied.	No dosage adjustment for levofloxacin appears to be required when co-administered with zidovudine.	

Legend: C = Case Study; CT = Clinical Trial; T = Theoretical

Drug-Food Interactions

Levofloxacin may be taken with or without food.

Drug-Herb Interactions

Interactions with herbal products have not been established.

Drug-Laboratory Interactions

Some quinolones, including levofloxacin, may produce false-positive urine screening results for opiates using commercially available immunoassay kits. Confirmation of positive opiate screens by more specific methods may be necessary.

Levofloxacin may interfere in the bacteriological diagnosis of tuberculosis and thus give falsenegative results; therefore, tuberculosis diagnostic tests should be repeated on the patient after termination of Levofloxacin in 5% Dextrose Injection treatment.

DOSAGE AND ADMINISTRATION

Dosing Considerations

The dosage of Levofloxacin in 5% Dextrose Injection for patients with normal renal function (i.e., $Cl_{Cr} > 80 \text{ mL/min}$) is described in the following dosing chart. For patients with altered renal function (i.e., $Cl_{Cr} < 80 \text{ mL/min}$), see the Patients with Impaired Renal Function subsection. The 250 mg and 500 mg doses of Levofloxacin in 5% Dextrose Injection should be administered by slow infusion over 60 minutes every 24 hours while the 750 mg dose is administered by slow infusion over 90 minutes every 24 hours.

Recommended Dose and Dosage Adjustment

Patients with Normal Renal Function

Infection*	Dose	Freq.	Duration
Acute Bacterial Exacerbation of Chronic Bronchitis	500 mg	q24h	7 days
	750 mg	q24h	5 days
Comm Acquired Pneumonia	500 mg	q24h	7-14 days (10-14 days for severe infections)
	750 mg**	q24h	5 days
Sinusitis	500 mg	q24h	10-14 days
	750 mg***	q24h	5 days
Nosocomial Pneumonia	750 mg	q24h	7-14 days
Uncomplicated SSSI	500 mg	q24h	7-10 days
Complicated SSSI	750 mg	q24h	7-14 days
Chronic Bacterial Prostatitis	500 mg	q24h	28 days
Complicated UTI	250 mg	q24h	10 days
	750 mg****	q24h	5 days
Acute Pyelonephritis	250 mg	q24h	10 days
	750 mg	q24h	5 days
Uncomplicated UTI	250 mg	q24h	3 days

* DUE TO THE DESIGNATED PATHOGENS (see INDICATIONS AND CLINICAL USE).

** Efficacy of this alternative regimen has only been documented for infections caused by penicillin-susceptible *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Haemophilus parainfluenzae*, *Mycoplasma pneumoniae*, *Chlamydia pneumoniae*, and *Legionella pneumophila*.

*** The efficacy of a regimen of 750 mg daily for 5 days has been demonstrated to be noninferior to a regimen of 500 mg daily for 10 days. The 750 mg daily 5-day regimen has not been compared to a regimen of 500 mg daily for 11-14 days.

**** The efficacy of this alternative regimen has been documented for infections caused by *Escherichia coli, Klebsiella pneumoniae,* and *Proteus mirabilis.* Efficacy against infections caused by *Enterococcus faecalis, Enterobacter cloacae,* or *Pseudomonas aeruginosa* has not been demonstrated with this regimen.

Patients with Impaired Renal Function

On the basis of the altered levofloxacin disposition pharmacokinetics in subjects with impaired renal function, dose adjustment is recommended for patients with impaired renal function as given below (see WARNINGS AND PRECAUTIONS: <u>Renal</u>; ACTION AND CLINICAL

PHARMACOLOGY: <u>Special Populations and Conditions</u>, Renal Insufficiency and *Product Monograph Part II*: DETAILED PHARMACOLOGY, <u>Factors Influencing the Pharmacokinetics</u>, Special Populations, <u>Renal Insufficiency</u>).

Dosing recommendations for renally impaired patients are based on data collected from a clinical safety and pharmacokinetic study in renally impaired patients treated with a single 500 mg oral dose of levofloxacin. There is no clinical experience available in this patient population for the 250 mg dose or 750 mg dose. Pharmacokinetic modelling was used to determine a recommended dosing regimen which would provide equivalent drug exposures for which clinical efficacy has been demonstrated. The potential effects of levofloxacin associated with possible increased serum/tissue levels in renal-impaired patients, such as effect on QTc interval, have not been studied.

Renal Status	Initial Dose	Subsequent Dose
Acute Sinusitis/Acute Bacterial Exacerb	ation of Chronic Bronchi	tis/Community-Acquired
Pneumonia/Uncomplicated SSSI/Chron	ic Bacterial Prostatitis	
Cl _{Cr} from 50 to 80 mL/min	No dosage adjustment req	uired
Cl _{Cr} from 20 to 49 mL/min	500 mg	250 mg q24h
Cl _{Cr} from 10 to 19 mL/min	500 mg	250 mg q48h
Hemodialysis	500 mg	250 mg q48h
CAPD	500 mg	250 mg q48h
Complicated UTI/Acute Pyelonephritis		
$Cl_{Cr} \ge 20 \text{ mL/min}$	No dosage adjustment req	uired
Cl _{Cr} from 10 to 19 mL/min	250 mg	250 mg q48h
Complicated SSSI/Nosocomial Pneumo	nia/Community-Acquired	Pneumonia/Acute Bacterial
Exacerbation of Chronic Bronchitis/Act	ute Sinusitis/Complicated	UTI/Acute Pyelonephritis
Cl _{Cr} from 50 to 80 mL/min	No dosage adjustment req	uired
Cl _{Cr} from 20 to 49 mL/min	750 mg	750 mg q48h
Cl _{Cr} from 10 to 19 mL/min	750 mg	500 mg q48h
Hemodialysis	750 mg	500 mg q48h
CAPD	750 mg	500 mg q48h
Uncomplicated UTI	No dosage adjustment rec	uired

 \overline{Cl}_{Cr} = creatinine clearances

CAPD = chronic ambulatory peritoneal dialysis

When only the serum creatinine is known, the following formula may be used to estimate creatinine clearance.

Men: Creatinine Clearance (mL/min) = $\underline{\text{Weight (kg) x (140 - age)}} \times 1.2 \text{ serum}$ creatinine (mcmol/L)

Women: $0.85 \times$ the value calculated for men.

The serum creatinine should represent a steady state of renal function.

Missed Dose

More than the prescribed dose of Levofloxacin in 5% Dextrose Injection should not be taken, even if a dose is missed.

Administration

Injection

CAUTION: RAPID OR BOLUS INTRAVENOUS INFUSION MUST BE AVOIDED. Levofloxacin in 5% Dextrose Injection should be infused intravenously, slowly over a period of not less than 60 minutes for a 250 mg or a 500 mg dose, and not less than 90 minutes for a 750 mg dose. Levofloxacin in 5% Dextrose Injection should only be administered by intravenous infusion. It is not for intramuscular, intrathecal, intraperitoneal, or subcutaneous administration (see WARNINGS AND PRECAUTIONS).

Levofloxacin in 5% Dextrose Injection in single-use flexible containers does not require further dilution. Consequently, each 50 mL, 100 mL and 150 mL of PREMIXED solution contains the equivalent of 250 mg, 500 mg and 750 mg of levofloxacin (5 mg/mL), respectively in 5% dextrose (D5W).

This parenteral drug product should be inspected visually for clarity, discoloration, particulate matter, precipitate, and leakage prior to administration. Samples containing visible particles should be discarded.

Since the premix flexible containers are for single use only, any unused portion should be discarded.

Since only limited data are available on the compatibility of levofloxacin intravenous injection with other intravenous substances, **additives or other medications should not be added to Levofloxacin in 5% Dextrose Injection or infused simultaneously through the same intravenous line.** If the same intravenous line is used for sequential infusion of several different drugs, the line should be flushed before and after infusion of Levofloxacin in 5% Dextrose Injection with an infusion solution compatible with Levofloxacin in 5% Dextrose Injection and with any other drug(s) administered via this common line.

Instructions for the Use of Levofloxacin in 5% Dextrose Injection in flexible containers

To open

- 1. Tear outer wrap at the notch and remove solution container.
- 2. Check the container for minute leaks by squeezing the inner bag firmly. If leaks are found, or if the seal is not intact, discard the solution, as the sterility may be compromised.
- 3. Do not use if the solution is cloudy or a precipitate is present.
- 4. Use sterile equipment.
- 5. WARNING: Do not use flexible containers in series connections. Such use could result in air embolism, due to residual air being drawn from the primary container, before administration of the fluid from the secondary container is complete.

Preparation for administration

- 1. Close flow control clamp of administration set.
- 2. Remove cover from port at bottom of container.
- 3. Insert piercing pin of administration set into port with a twisting motion until the pin is

firmly seated. NOTE: See full directions on administration set carton.

- 4. Suspend container from hanger.
- 5. Squeeze and release drip chamber to establish proper fluid level in chamber during infusion of Levofloxacin in 5% Dextrose Injection in flexible containers.
- 6. Open flow control clamp to expel air from set. Close clamp.
- 7. Regulate rate of administration with flow control clamp.

OVERDOSAGE

In the event of an acute overdosage, activated charcoal may be administered to aid in the removal of unabsorbed drug. General supportive measures are recommended. The patient should be observed, including ECG monitoring (see **ACTION AND CLINICAL PHARMACOLOGY:** <u>**Pharmacodynamics**</u>, <u>Studies Measuring Effects on QT and Corrected</u> <u>QT (QTc) Intervals</u>), and appropriate hydration maintained. Treatment should be supportive. Levofloxacin is not efficiently removed by hemodialysis or peritoneal dialysis.

Levofloxacin exhibits a low potential for acute toxicity. Mice, rats, dogs and monkeys exhibited the following clinical signs after receiving a single high dose of levofloxacin: ataxia, ptosis, decreased locomotor activity, dyspnea, prostration, tremors, and convulsions. Doses in excess of 1500 mg/kg orally and 250 mg/kg IV produced significant mortality in rodents.

For management of a suspected drug overdose, contact your regional Poison Control Centre immediately.

ACTION AND CLINICAL PHARMACOLOGY

Mechanism of Action

Levofloxacin is a synthetic broad-spectrum antibacterial agent for intravenous administration.

Levofloxacin is the L-isomer of the racemate, ofloxacin, a quinolone antibacterial agent. The antibacterial activity of ofloxacin resides primarily in the L-isomer. The mechanism of action of levofloxacin and other quinolone antibacterials involves inhibition of bacterial topoisomerase II (DNA gyrase) and topoisomerase IV. Topoisomerases are essential in controlling the topological state of DNA, and are vital for DNA replication, transcription, repair and recombination.

Fluoroquinolones, including levofloxacin, differ in chemical structure and mode of action from other classes of antimicrobial agents, such as β -lactam antibiotics, aminoglycosides, and macrolides. Therefore, microorganisms resistant to these latter classes of antimicrobial agents may be susceptible to fluoroquinolones. For example, β -lactamase production and alterations in penicillin-binding proteins have no effect on levofloxacin activity. Conversely, microorganisms resistant to fluoroquinolones may be susceptible to other classes of antimicrobial agents.

Pharmacodynamics

<u>Studies Measuring Effects on QT and Corrected QT (QTc) Intervals</u> Two studies have been conducted to assess specifically the effect of levofloxacin on QT and corrected QT (QTc) intervals in healthy adult volunteers. In a dose escalation study (n=48) where the effect on average QTc, after single doses of 500, 1000, and 1500 mg of levofloxacin, was measured between the baseline QTc (calculated as the average QTc measured 24, 20, 16 hours and immediately before treatment) and the average post-dose OTc interval (calculated from measurements taken every half hour for two hours and at 4, 8, 12 and 24 hours after treatment), an effect on the average QTc (Bazett) was -1.84, 1.55 and 6.40 msec, respectively. In a study which compared the effect of 3 antimicrobials (n=48) where the difference was measured between the baseline QTc (calculated as the average QTc measured 24, 20, 16 hours and immediately before treatment) and the average post-dose OTc interval (calculated from measurements taken every half hour for four hours and at 8, 12 and 24 hours after treatment), an effect on the average QTc was an increase of 3.58 msec after the 1000 mg dose of levofloxacin. The mean increase compared to baseline of QTc at C_{max} in these two trials was 7.82 msec and 5.32 msec after a single 1000 mg dose. In these trials, no effect on QT intervals compared to placebo was evident at any of the doses studied. The clinical relevance of the results of these studies is not known (see Product Monograph Part II: DETAILED PHARMACOLOGY, Human Pharmacology, Studies Measuring the Effects on OT and Corrected OT (OTc) Intervals).

Pharmacokinetics

The mean (\pm SD) pharmacokinetic parameters of levofloxacin determined under single and steady-state conditions following oral (p.o.) or intravenous (i.v.) doses of levofloxacin are summarized in Table 1.5.

 Table 1.5: Summary of Pharmacokinetic Parameters (mean ± SD)

Regimen	Ν	C _{max} (µg/mL)	T _{max} (h)	AUC ^J (µg*h/mL)	CL/F (mL/min)	Vd/F (L)	t _{1/2} (h)	Cl _r (mL/min)

ND = Not Determined

Absorption:

Oral

Levofloxacin is rapidly and essentially completely absorbed after oral administration. Peak plasma concentrations are usually attained 1 to 2 hours after oral dosing. The absolute bioavailability of a 500 mg tablet and a 750 mg tablet of levofloxacin is approximately 99% in both cases, demonstrating complete oral absorption of levofloxacin. Levofloxacin pharmacokinetics are linear and predictable after single and multiple oral dosing regimens. Steady-state conditions are reached within 48 hours following a 500 mg or 750 mg once-daily dosage regimen. The peak and trough plasma concentrations attained following multiple once-daily oral dosage regimens were approximately 5.7 mcg/mL and 0.5 mcg/mL after the 500 mg doses, and 8.6 mcg/mL and 1.1 mcg/mL after the 750 mg doses, respectively.

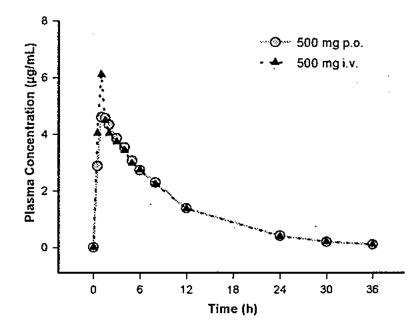

There was no clinically significant effect of food on the extent of absorption of levofloxacin. Oral administration with food slightly prolongs the time to peak concentration by approximately 1 hour, and slightly decreases the peak concentration by approximately 14%. Therefore, levofloxacin can be administered without regard to food.

<u>I.V.</u>

Following a single intravenous dose of levofloxacin to healthy volunteers, the mean peak plasma concentration attained was 6.2 mcg/mL after a 500 mg dose infused over 60 minutes, and 7.99 mcg/mL after a 750 mg dose infused over 90 minutes. Levofloxacin pharmacokinetics are linear and predictable after single and multiple i.v. dosing regimens. Steady-state conditions are reached within 48 hours following a 500 mg or 750 mg once-daily dosing regimen. The peak and trough plasma concentrations attained following multiple once-daily i.v. regimens were approximately 6.4 mcg/mL and 0.6 mcg/mL after the 500 mg doses, and 7.92 mcg/mL and 0.85 mcg/mL after the 750 mg doses, respectively.

The plasma concentration profile of levofloxacin after i.v. administration is similar and comparable in extent of exposure (AUC) to that observed for levofloxacin tablets when equal doses (mg/mg) are administered. Therefore, the oral and i.v. routes of administration can be considered interchangeable (see following figure).

Mean Levofloxacin Plasma Concentration:Time Profiles

Distribution:

The mean volume of distribution of levofloxacin generally ranges from 74 to 112 L after single and multiple 500 mg or 750 mg doses, indicating widespread distribution into body tissues. Levofloxacin reaches its peak levels in skin tissues (11.7 mcg/g for a 750 mg dose) and in blister fluid (4.33 mcg/g for a 500 mg dose) at approximately 3-4 hours after dosing. The skin tissue biopsy to plasma AUC ratio is approximately 2. The blister fluid to plasma AUC ratio is approximately 1, following multiple once-daily oral administration of 750 mg and 500 mg levofloxacin to healthy subjects, respectively. Levofloxacin also penetrates into lung tissues. Lung tissue concentrations were generally 2- to 5-fold higher than plasma concentrations, and ranged from approximately 2.4 to 11.3 mcg/g over a 24-hour period after a single 500 mg oral dose.

Levofloxacin is 24 to 38% bound to serum proteins across all species studied. Levofloxacin binding to serum proteins is independent of the drug concentration.

Metabolism:

Levofloxacin is stereochemically stable in plasma and urine, and does not invert metabolically to its enantiomer, D-ofloxacin. Levofloxacin undergoes limited metabolism in humans, and is primarily excreted as unchanged drug (87%) in the urine within 48 hours.

Excretion:

The major route of elimination of levofloxacin in humans is as unchanged drug in the urine. The mean terminal plasma elimination half-life of levofloxacin ranges from approximately 6 to 8 hours following single or multiple doses of levofloxacin given intravenously.

Special Populations and Conditions

Pediatrics: The pharmacokinetics of levofloxacin in pediatric patients have not been studied.

Geriatrics: There are no significant differences in levofloxacin pharmacokinetics between young and elderly subjects when the subjects' differences in creatinine clearance are taken into consideration. Drug absorption appears to be unaffected by age. Levofloxacin dose adjustment based on age alone is not necessary.

Gender: There are no significant differences in levofloxacin pharmacokinetics between male and female subjects when the differences in creatinine clearance are taken into consideration. Dose adjustment based on gender alone is not necessary.

Race: The apparent total body clearance and apparent volume of distribution were not affected by race in a covariate analysis performed on data from 72 subjects.

Hepatic Insufficiency: Pharmacokinetic studies in hepatically impaired patients have not been conducted. Due to the limited extent of levofloxacin metabolism, the pharmacokinetics of levofloxacin are not expected to be affected by hepatic impairment.

Renal Insufficiency: Pharmacokinetic parameters of levofloxacin following oral or intravenous doses of levofloxacin in patients with impaired renal function (creatinine clearance ≤ 80 mL/min) are presented in Table 1.5. Clearance of levofloxacin is reduced and plasma elimination half-life is prolonged in this patient population. Dosage adjustment may be required in such patients to avoid accumulation.

A dosage reduction is being recommended depending on the levels of renal insufficiency. Dosing recommendations are based on pharmacokinetic modelling of data collected from a clinical safety and pharmacokinetic study in renally impaired patients treated with a single 500 mg oral dose of levofloxacin (see WARNINGS AND PRECAUTIONS: Renal, and DOSAGE AND ADMINISTRATION: Recommended Dose and Dosage Adjustment, <u>Patients with Impaired Renal Function</u>).

Neither hemodialysis nor continuous ambulatory peritoneal dialysis (CAPD) is effective in removal of levofloxacin from the body, indicating supplemental doses of levofloxacin are not required following hemodialysis or CAPD.

Bacterial Infection: The pharmacokinetics of levofloxacin in patients with community-acquired bacterial infections are comparable to those observed in healthy subjects.

STORAGE AND STABILITY

Injection

When stored under recommended conditions, Levofloxacin in 5% Dextrose Injection, as supplied in flexible containers, is stable through the expiration date printed on the label.

Levofloxacin in 5% Dextrose Injection in flexible containers should be stored at 15-30°C. Avoid excessive heat and protect from freezing and light. Store with protective overwrap and use immediately once removed from the overwrap.

DOSAGE FORMS, COMPOSITION AND PACKAGING

Levofloxacin in 5% Dextrose Injection

Levofloxacin in 5% Dextrose Injection in flexible containers is a sterile, preservative-free, nonpyrogenic premixed solution that contains levofloxacin, at 5 mg/mL in 5% dextrose (D₅W). The solution has a pH ranging from 3.8 to 5.8. Solutions of hydrochloric acid and/or sodium hydroxide may have been added to adjust the pH.

Levofloxacin in 5% Dextrose Injection is supplied in single-use flexible containers containing a premixed, ready-to-use levofloxacin solution in D_5W in the following formats:

- containers of 100 mL capacity containing 50 or 100 mL of PREMIXED solution
- containers of 250 mL capacity containing 150 mL of PREMIXED solution

Prior to use, it is important to check for leaks by squeezing the inner bag firmly.

NO FURTHER DILUTION OF THESE PREPARATIONS IS NECESSARY. Consequently, each 50 mL, 100 mL and 150 mL of premixed solution contains the equivalent of 250 mg, 500 mg and 750 mg of levofloxacin (5 mg/mL), respectively in 5% dextrose (D5W).

PART II: SCIENTIFIC INFORMATION

PHARMACEUTICAL INFORMATION

Drug Substance

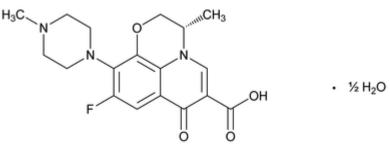

Proper name: levofloxacin

Chemical name: (-)-(S)-9-Fluoro-2,3-dihydro-3-methyl-10-(4-methyl-1-piperazinyl)-7-oxo-*7H*-pyrido[1,2,3-*de*]-1,4-benzoxazine-6-carboxylic acid hemihydrate

Molecular formula: $C_{18}H_{20}FN_3O_4 \bullet \frac{1}{2}H_2O$

Molecular mass: 370.38 g/mol

Structural formula:

Physicochemical properties:

Levofloxacin is a light yellowish white to yellow-white crystal or crystalline powder with a melting point of 225-227°C. The pH of a 1.0% aqueous solution is 7.16, and the pKa value for levofloxacin is 6.25.

Soluble in dimethylsulphoxide and in acetic acid. Sparingly soluble in water, in acetone and in methanol. Practically insoluble in glycerin and in n-octanol.

^b success rates include the clinical response category of cured and improved

^c two-sided 95% CIs (with continuity correction) around the difference in response rates

^d 7-14 days after last dose of active study medication for microbiologically evaluable population

In the clinically evaluable population (31-38 days after enrollment) pneumonia was observed in 7 out of 151 patients in the levofloxacin 750 mg group and 2 out of 147 patients in the levofloxacin 500 mg group. Given the small numbers observed, the significance of this finding cannot be determined statistically.

Chlamydia pneumoniae	20/22 (90.9)
Legionella pneumophila	12/12 (100.0)

7 to 14 Day Treatment Regimen

In three North American clinical studies, of 655 patients treated with levofloxacin for community-acquired pneumonia, 45 clinically and microbiologically evaluable patients were defined as severely ill by study criteria and met American Thoracic Society criteria for severe community-acquired pneumonia (American Thoracic Society, 1993). Clinical success (cure and improvement) was achieved in 98% of these 45 patients. Data on the treatment of patients with severe Legionella pneumonia is limited to one patient.

Data on the treatment of community-acquired pneumonia due to penicillin-resistant *S. pneumoniae* is limited to 12 evaluable patients from the combined clinical trials database. Of these, 4 were considered to have been severe. All 12 patients achieved clinical success (see **MICROBIOLOGY**).

The following tables describe the results from the two pivotal trials for community-acquired pneumonia (7-14 day treatment regimen).

Study Number	Levofloxacin n/N (%)	Comparator n/N (%)	95% Confidence Interval

DETAILED PHARMACOLOGY

Animal Pharmacology

Pharmacodynamics

A summary of the major findings obtained from animal pharmacology studies with levofloxacin is presented below:

Table 2.47 - Summary of Major Nonclinical Pharmacological Effects of Levofloxacin

System	Species	Major Findings
Central Nervous System	mouse	≥600 mg/kg, p.o., decreased spontaneous locomotor activity, CNS depression, decreased pinna reflex, decrease writhing response to acetic acid; increased incidences of strychnine-, pentylenetetrazol- and caffeine-induced convulsions; ≥200 mg/kg, i.v., convulsions after rapid injection, decreased spontaneous motor activity, muscle tone, posture, body temperature; increased respiratory rate; prolonged hexobarbital sleep time
	rat	At 200 mg/kg, i.v., inhibition of conditioned-avoidance response; At 200 mg/kg, i.p., increased spontaneous motor activity, lowered

		body posture, increased restlessness
	rabbit	At 200 mg/kg, p.o., decrease in body temperature
	cat	≥ 6 mg/kg, i.v., decreased spinal reflex;
		\geq 30 mg/kg, i.v., increased EEG awake stage, seizure discharges
Autonomic Nervous	cat	At 20 mg/kg, i.v., reduced contractile response of nictitating
System		membrane to pre-and postganglionic stimulation; suppression of
		acetylcholine depressor response
Cardiopulmonary System	dog	≥6 mg/kg, i.v. bolus, decreases in blood pressure, left ventricular
		pressure, respiration depth; $\leq 10 \text{ mg/kg}$, i.v. infusion, no effect on
		blood pressure; ≥ 20 mg/kg, i.v. infusion, decrease in blood pressure,
		decrease in cardiac output and stroke volume; increase in serum
		histamine concentrations
Gastrointestinal System	mouse	At 200 mg/kg, i.v., inhibition of gastric propulsion
	rat	\geq 200 mg/kg, p.o., decrease in gastric fluid volume, total acidity,
		pepsin output; increase in gastric fluid pH; at 600 mg/kg, decrease in
		gastric emptying; at 200 mg/kg, i.v., decrease in gastric fluid volume,
		acid and pepsin output and gastric emptying; increase in gastric pH
Urinary Tract	rat	\geq 200 mg/kg, p.o., decrease in urinary volume and electrolyte
		excretion; at 200 mg/kg, i.v., decrease in urinary volume
Inflammation	rat	At 600 mg/kg, p.o., inhibition of carrageenan-induced foot edema
Isolated Smooth Muscle		On dog mesenteric, renal, femoral, and basilar arteries,
		inhibition of norepinephrine-induced contractions $\geq 10 \times 10^{-6}$ M;
		competitive inhibition of phenylephrine-induced contractions of
		rabbit thoracic artery

In mice, the CNS stimulatory effect of quinolones is enhanced by concomitant administration of non-steroidal anti-inflammatory drugs.

In vitro and *in vivo* studies in animals indicate that levofloxacin is neither an enzyme inducer nor inhibitor in the human therapeutic plasma concentration range; therefore, no drug metabolizing enzyme-related interactions with other drugs or agents are anticipated.

Human Pharmacology

Pharmacodynamics

Studies Measuring the Effects on QT and Corrected QT (QTc) Intervals

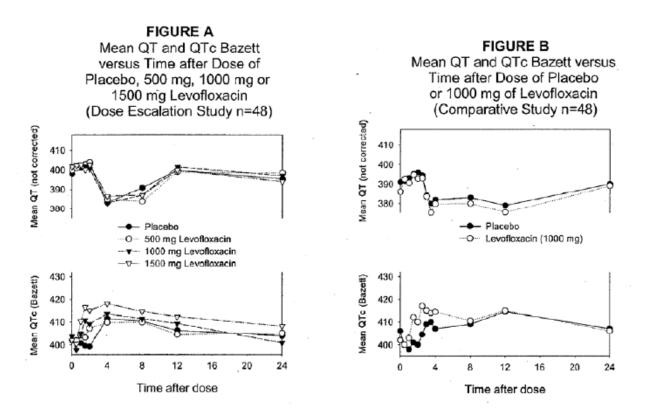

Two double-blind, placebo-controlled studies assessing the effect of levofloxacin on QTc intervals in healthy male and female volunteers 18-84 years of age were conducted. Each had a four-treatment crossover, single-dose study design. One study evaluated dose-response. The other was a comparative study that involved measuring the effects of doses of levofloxacin and two other fluoroquinolones. In this comparative study, subjects were given twice the doses of these antibiotics that are recommended for the treatment of otherwise healthy subjects with community-acquired pneumonia. In both trials, no effect on QT intervals compared to placebo was evident at any of the doses of levofloxacin studied (top panels of figure A and figure B).

Dose escalation study (Figure A): In this trial, the mean change in the average QTc interval (calculated from measurements taken every half hour for two hours and at 4, 8, 12 and 24 hours

after treatment) from the baseline QTc (calculated as the average QTc measured 24, 20, 16 hours and immediately before treatment) was a decrease of 1.84 msec after treatment with 500 mg, an increase of 1.55 msec after treatment with 1000 mg of levofloxacin and an increase of 6.40 msec after treatment with 1500 mg. The change in QTc interval at Cmax (calculated using the Bazett formula) after treatment with 500 mg of levofloxacin was not significantly different from that measured after treatment with placebo. In this trial, the mean change in the QTc (Bazett) at Cmax from baseline QTc (calculated as the average QTc measured 24, 20, 16 hours and immediately before treatment) was -3.20 msec after treatment with 500 mg of levofloxacin, 7.82 msec after treatment with 1000 mg of levofloxacin and 10.58 msec after treatment with 1500 mg of levofloxacin.

Comparative, placebo-controlled study (Figure B; only levofloxacin and placebo data shown): In this study, the mean change in the average QTc interval (calculated from measurements taken every half hour for four hours and at 8, 12 and 24 hours after treatment)

from the baseline QTc (calculated as the average QTc measured 24, 20, 16 hours and immediately before treatment) was 3.58 msec after treatment with 1000 mg levofloxacin. In this study, the change in the QTc (Bazett) at Cmax from a baseline QTc (calculated as the average QTc measured 24, 20, 16 hours and immediately before treatment) was 5.32 msec after treatment with 1000 mg of levofloxacin.

Pharmacokinetics

Absorption

Oral

Levofloxacin is rapidly and essentially completely absorbed after oral administration. Peak plasma concentrations are usually attained 1 to 2 hours after oral dosing. The absolute bioavailability of a 500 mg tablet and a 750 mg tablet of levofloxacin is approximately 99% in

both cases, demonstrating complete oral absorption of levofloxacin. Levofloxacin pharmacokinetics are linear and predictable after single and multiple oral dosing regimens. After single oral doses of 250 to 1000 mg of levofloxacin to healthy subjects, plasma concentrations increase proportionally with the dose as shown (mean \pm SD):

Oral Dose	n	Peak Plasma Concentration	Area Under the Curve
mg		mcg/mL	AUC _{0-∞} , mcg.h/mL
250	15	2.8 ± 0.4	27.2 ± 3.9
500	23	5.1 ± 0.8	47.9 ± 6.8
750	10	7.1 ± 1.4	82.2 ± 14.3
1000	10	8.9 ± 1.9	111.0 ± 20.8

Steady-state conditions are reached within 48 hours following 500 mg or 750 mg once-daily dosage regimens. The peak and trough plasma concentrations attained following multiple oncedaily oral dosage regimens were approximately 5.7 and 0.5 mcg/mL after the 500 mg doses, and 8.6 and 1.1 mcg/mL after the 750 mg doses, respectively.

Oral administration with food slightly prolongs the time to peak concentration by approximately 1 hour and slightly decreases the peak concentration by approximately 14%.

Intravenous

Levofloxacin pharmacokinetics are linear and predictable after single and multiple i.v. dosing regimens. Following a single intravenous dose of levofloxacin to healthy volunteers, the mean peak plasma concentration attained was 6.2 mcg/mL after a 500 mg dose infused over 60 minutes and 7.99 mcg/mL after a 750 mg dose infused over 90 minutes. Steady-state conditions are reached within 48 hours following a 500 mg or 750 mg once-daily dosing regimen. The peak and trough plasma concentrations attained following multiple once-daily i.v. regimens were approximately 6.4 mcg/mL and 0.6 mcg/mL after the 500 mg doses, and 7.92 mcg/mL and 0.85 mcg/mL after the 750 mg doses, respectively.

The plasma concentration profile of levofloxacin after i.v. administration is similar and comparable in extent of exposure (AUC) to that observed for levofloxacin tablets when equal doses (mg/mg) are administered. Therefore, the oral and i.v. routes of administration can be considered interchangeable.

Distribution

The mean volume of distribution of levofloxacin generally ranges from 74 to 112 L after single and multiple 500 mg or 750 mg doses, indicating widespread distribution into body tissues. Levofloxacin reaches its peak levels in skin tissues (11.7 mcg/g for a 750 mg dose) and in blister fluid (4.33 mcg/g for a 500 mg dose) at approximately 3-4 hours after dosing. The skin tissue biopsy to plasma AUC ratio is approximately 2. The blister fluid to plasma AUC ratio is approximately 1, following multiple once-daily oral administration of 750 mg and 500 mg levofloxacin to healthy subjects, respectively. Levofloxacin also penetrates into lung tissues. Lung tissue concentrations were generally 2- to 5-fold higher than plasma concentrations and range from approximately 2.4 to 11.3 mcg/g over a 24-hour period after a single 500 mg dose. Levofloxacin also penetrates into cortical and spongiosa bone tissues in both the femoral head and distal femur. Peak levofloxacin concentrations in these tissues ranging from 2.4 to 15 mcg/g were generally attained by 2 to 3 hours after a single 500 mg oral dose. In vitro, over a clinically relevant range (1 to 10 mcg/mL) of serum/plasma levofloxacin concentrations, levofloxacin is approximately 24 to 38% bound to serum proteins across all species studied, as determined by the equilibrium dialysis method. Levofloxacin is mainly bound (approximately 21 to 30%) to serum albumin in humans. Levofloxacin binding to serum proteins is independent of the drug concentration.

Metabolism

Levofloxacin is stereochemically stable in plasma and urine, and does not invert metabolically to its enantiomer, D-ofloxacin. Levofloxacin undergoes limited metabolism in humans and is primarily excreted as unchanged drug in the urine. Following oral administration, approximately 87% of an administered dose was recovered as unchanged drug in urine within 48 hours, whereas less than 4% of the dose was recovered in feces in 72 hours. Less than 5% of an administered dose was recovered in the urine as the desmethyl and N-oxide metabolites, the only metabolites identified in humans. These metabolites have little relevant pharmacological activity.

Excretion

The major route of elimination of levofloxacin in humans is as unchanged drug in the urine. The mean terminal plasma elimination half-life of levofloxacin ranges from approximately 6 to 8 hours following single or multiple doses of levofloxacin given orally or intravenously. The mean apparent total body clearance and renal clearance range from approximately 144 to 226 mL/min and 96 to 142 mL/min, respectively. Renal clearance in excess of the glomerular filtration rate suggests that tubular secretion of levofloxacin occurs in addition to its glomerular filtration. Concomitant administration of either cimetidine or probenecid results in approximately 24% and 35% reduction in the levofloxacin renal clearance, indicating that secretion of levofloxacin occurs in the renal proximal tubule. No levofloxacin crystals were found in any of the urine samples freshly collected from subjects receiving levofloxacin.

Factors Influencing the Pharmacokinetics

Special Populations

Elderly

There are no significant differences in levofloxacin pharmacokinetics between young and elderly subjects when the subjects' differences in creatinine clearance are taken into consideration. Following a 500 mg oral dose of levofloxacin to healthy elderly subjects (66 - 80 years of age), the mean terminal plasma elimination half-life of levofloxacin was about 7.6 hours, as compared to approximately 6 hours in younger adults. The difference was attributable to the variation in renal function status of the subjects and was not believed to be clinically significant. Drug absorption appears to be unaffected by age. Levofloxacin dose adjustment based on age alone is not necessary.

Pediatric

The pharmacokinetics of levofloxacin in pediatric patients have not been studied.

Gender

There are no significant differences in levofloxacin pharmacokinetics between male and female subjects when the differences in creatinine clearance are taken into consideration. Following a 500 mg oral dose of levofloxacin to healthy male subjects, the mean terminal plasma elimination half-life of levofloxacin was about 7.5 hours, as compared to approximately 6.1 hours in female

subjects. This difference was attributable to the variation in renal function status of the male and female subjects, and was not believed to be clinically significant. Drug absorption appears to be unaffected by the gender of the subjects. Dose adjustment based on gender alone is not necessary.

Race

The effect of race on levofloxacin pharmacokinetics was examined through a covariate analysis performed on data from 72 subjects: 48 white and 24 nonwhite. The apparent total body clearance and apparent volume of distribution were not affected by the race of the subjects.

Renal Insufficiency

Clearance of levofloxacin is reduced and plasma elimination half-life is prolonged in patients with impaired renal function (creatinine clearance ≤ 80 mL/min). Dosage adjustment may be required in such patients to avoid levofloxacin accumulation. Neither hemodialysis nor continuous ambulatory peritoneal dialysis (CAPD) is effective in removal of levofloxacin from the body, indicating supplemental doses of levofloxacin are not required following hemodialysis or CAPD (see ACTION AND CLINICAL PHARMACOLOGY: <u>Pharmacokinetics</u>; WARNINGS AND PRECAUTIONS: <u>Renal</u>, and DOSAGE AND ADMINISTRATION).

Plasma Ratio

Comparison of the expected steady-state AUC values^a in renally impaired patients relative to those in patients with normal renal function:

	Creatinine Clearance 50-80 mL/min receiving 500 mg q24h	Creatinine Clearance 20-49 mL/min receiving 250 mg q24h	Creatinine Clearance < 20 mL/min receiving 250 mg q48h
AUC value relative to patients with normal renal function receiving 500 mg q24h	172%	183%	139%
AUC value relative to patients with normal renal function receiving 500 mg q12h	89%	94%	71%

^a Values were extrapolated from the mean levofloxacin plasma concentration-time data in subjects with normal renal function (n = 23) and subjects with impaired renal function (n = 3 for Cl_{Cr} 50 - 80 mL/min, n = 8 for Cl_{Cr} 20 – 49 mL/min, and n = 6 for Cl_{Cr} 20 mL/min)

Urine Concentrations

The mean \pm SD concentrations (mcg/mL) of levofloxacin in the urine following a 500 mg p.o. dose of levofloxacin in subjects with impaired renal function are summarized as follows^a:

	Cl _{Cr} 50-80 mL/min	Cl _{Cr} 20-49 mL/min	Cl _{Cr} <20 mL/min
Collection Interval	n ^b = 3	n = 8	n = 6
0 - 6 h	185±61.7	98.1±48.1	66.5±27.3
6 - 12 h	91.6±24.4	75.2±22.1	39.0±23.1
12 - 24 h	156±183	58.6±31.1	29.5±20.7
24 - 36 h	49.7±16.2	44.1±10.6	<25
36 - 48 h	<25	<25	<25

^a Limit of quantitation = 25 ug/mL

^b n = number of subjects

Expected steady-state urinary concentrations (mcg/mL) of levofloxacin in renally impaired patients with the recommended adjusted dose regimen in the treatment of complicated UTI and acute pyelonephritis^a:

	Cl _{Cr} 50-80 mL/min	Cl _{Cr} 20-49 mL/min	Cl _{Cr} <20 mL/min
Collection Interval	receiving 250 mg q24h	receiving 250 mg q24h	receiving 250 mg q24h
0 - 6 h	161	103	54
6 - 12 h	61	76	29
12 - 24 h	40	58	24
24 - 36 h			23
36 - 48 h			16

a Values were extrapolated from the mean pharmacokinetic profiles in subjects with impaired renal function (n = 12 for Cl_{Cr} 50 - 80 rnL/min, n = 8 for Cl_{Cr} 20 - 49 mL/min, and n = 6 for Cl_{Cr} < 20 mL/min).

Hepatic Insufficiency

Pharmacokinetic studies in hepatically impaired patients have not been conducted. Due to the limited extent of levofloxacin metabolism, the pharmacokinetics of levofloxacin are not expected to be affected by hepatic impairment.

Bacterial Infection

The pharmacokinetics of levofloxacin in patients with serious community-acquired bacterial infections are comparable to those observed in healthy subjects.

HIV Infection

The pharmacokinetics of levofloxacin in HIV seropositive subjects (with CD4 cell counts ranging from 17 to 772) are comparable to those observed in healthy subjects.

Drug-Drug Interactions

The potential for pharmacokinetic drug interactions between levofloxacin and theophylline, warfarin, cyclosporine, digoxin, probenecid, cimetidine, sucralfate, zidovudine and antacids has been evaluated (see **DRUG INTERACTIONS**).

MICROBIOLOGY

Levofloxacin is the L-isomer of the racemate, ofloxacin, a quinolone antibacterial agent. The antibacterial activity of ofloxacin resides primarily in the L-isomer. The mechanism of action of levofloxacin and other quinolone antibacterials involves inhibition of bacterial topoisomerase II (DNA gyrase) and topoisomerase IV, enzymes required for DNA replication, transcription, repair, and recombination. In this regard, the L-isomer produces more hydrogen bonds and therefore, more stable complexes with DNA gyrase than does the D-isomer. Microbiologically, this translates into a 25- to 40-fold greater antibacterial activity for the L-isomer, levofloxacin, over the D-isomer. Quinolones rapidly and specifically inhibit bacterial DNA synthesis.

Levofloxacin has in vitro activity against a broad spectrum of gram-positive and gram-negative aerobic and anaerobic bacteria. Levofloxacin is often bactericidal at concentrations equal to or greater than the Minimum Inhibitory Concentrations (MIC). The in vitro activity of levofloxacin

against clinical isolates is summarized in Table 2.48.

Organism	(# of		MIC (mcg	/mL)

Streptococcus sanguis	(19)	1.000	2.000	0.250-	2.000	

* As with other drugs in this class, some strains of *Pseudomonas aeruginosa* may develop resistance fairly rapidly during treatment with levofloxacin.

** Data obtained for isolates from Complicated Skin and Skin Structure clinical studies, and literature, indicate the MIC value has increased for MRSA (see INDICATIONS AND CLINICAL USE for approved organisms). *Based on NCCLS classification

Levofloxacin is not active against *Treponema pallidum* (see WARNINGS AND PRECAUTIONS: Sexually Transmitted Diseases).

Resistance

Resistance to levofloxacin due to spontaneous mutation in vitro is a rare occurrence (range: 10⁻⁹ to 10⁻¹⁰). Although cross-resistance has been observed between levofloxacin and other fluoroquinolones, some organisms resistant to other quinolones, including ofloxacin, may be susceptible to levofloxacin.

Susceptibility Tests

Susceptibility testing for levofloxacin should be performed, as it is the optimal predictor of activity.

Dilution Techniques

Quantitative methods are used to determine antimicrobial minimal inhibitory concentrations

(MICs). These MICs provide estimates of the susceptibility of bacteria to antimicrobial compounds. The MICs should be determined using a standardized procedure. Standardized procedures are based on a dilution method*¹ (broth or agar) or equivalent with standardized inoculum concentrations and standardized concentrations of levofloxacin powder. The MIC values should be interpreted according to the following criteria:

For testing aerobic microorganisms other than *Haemophilus influenzae*, *Haemophilus parainfluenzae*, and *Streptococcus pneumoniae*:

MIC (mcg/mL)	Interpretation
≤ 2	Susceptible (S)
4	Intermediate (I)
≥ 8	Resistant (R)

For testing Haemophilus influenzae and Haemophilus parainfluenzae a:

MIC (mcg/mL)	Interpretation
≤ 2	Susceptible (S)
^a These interpretive standards are applicable only	y to broth microdilution susceptibility testing with
Haemophilus influenzae and Haemophilus parai	influenzae using Haemophilus Test Medium* ¹ .

The current absence of data on resistant strains precludes defining any categories other than "Susceptible". Strains yielding MIC results suggestive of a "nonsusceptible" category should be submitted to a reference laboratory for further testing.

For testing Streptococcus pneumoniae:b

MIC (mcg/mL)	Interpretation
≤ 2	Susceptible (S)
4	Intermediate (I)
≥ 8	Resistant (R)
1 1. 11 1	i a san e 🔪 ana

^b These interpretive standards are applicable only to broth microdilution susceptibility tests using cation-adjusted Mueller-Hinton broth with 2-5% lysed horse blood.

A report of "Susceptible" indicates that the pathogen is likely to be inhibited if the antimicrobial compound in the blood reaches the concentrations usually achievable. A report of "Intermediate" indicates that the result should be considered equivocal, and, if the microorganism is not fully susceptible to alternative, clinically feasible drugs, the test should be repeated. This category implies possible clinical applicability in body sites where the drug is physiologically concentrated or in situations where a high dosage of drug can be used. This category also provides a buffer zone which prevents small uncontrolled technical factors from causing major discrepancies in interpretation. A report of "Resistant" indicates that the pathogen is not likely to be inhibited if the antimicrobial compound in the blood reaches the concentrations usually achievable; other therapy should be selected.

Standardized susceptibility test procedures require the use of laboratory control microorganisms to control the technical aspects of the laboratory procedures. Standard levofloxacin powder should give the following MIC values:

Microorganism		MIC (mcg/mL)
Enterococcus faecalis	ATCC 29212	0.25 - 2
Escherichia coli	ATCC 25922	0.008 - 0.06
Escherichia coli	ATCC 35218	0.015 - 0.06
Pseudomonas aeruginosa	ATCC 27853	0.5 - 4
Staphylococcus aureus	ATCC 29213	0.06 - 0.5
Haemophilus influenzae	ATCC 49247 ^c	0.008 - 0.03
Streptococcus pneumoniae	ATCC 49619 ^d	0.5 - 2

^c This quality control range is applicable to only *H. influenzae* ATCC 49247 tested by a broth microdilution procedure using Haemophilus Test Medium (HTM)*¹.

^d This quality control range is applicable to only *S. pneumoniae* ATCC 49619 tested by a broth microdilution procedure using cation-adjusted Mueller-Hinton broth with 2-5% lysed horse blood.

Diffusion Techniques

Quantitative methods that require measurement of zone diameters also provide reproducible estimates of the susceptibility of bacteria to antimicrobial compounds. One such standardized procedure*² requires the use of standardized inoculum concentrations. This procedure uses paper disks impregnated with 5 mcg levofloxacin to test the susceptibility of microorganisms to levofloxacin. Reports from the laboratory, providing results of the standard single-disk susceptibility test with a 5 mcg levofloxacin disk, should be interpreted according to the following criteria:

For aerobic microorganisms other than *Haemophilus influenzae*, *Haemophilus parainfluenzae*, *Streptococcus pneumoniae* and *Nisseria gonorrhoeae*:

Zone diameter (mm)	Interpretation
≥ 17	Susceptible (S)
14-16	Intermediate (I)
≤13	Resistant (R)

For Haemophilus influenzae and Haemophilus parainfluenzae:^e

Zone diameter (mm)	Interpretation
≥ 17	Susceptible (S)

^e These interpretive standards are applicable only to disk diffusion susceptibility testing with Haemophilus influenzae and Haemophilus parainfluenzae using Haemophilus Test Medium* (HTM)².

The current absence of data on resistant strains precludes defining any categories other than "Susceptible". Strains yielding zone diameter results suggestive of a "Nonsusceptible" category should be submitted to a reference laboratory for further testing.

For Streptococcus pneumoniae:

Zone diameter (mm)	Interpretation
≥ 17	Susceptible (S)
14-16	Intermediate (I)

 ≤ 13 Resistant (R) ^f These zone diameter standards for *Streptococcus pneumoniae* apply only to tests performed using Mueller-Hinton agar supplemented with 5% sheep blood and incubated in 5% CO₂.

Interpretation should be as stated above for results using dilution techniques. Interpretation involves correlation of the diameter obtained in the disk test with the MIC for levofloxacin.

As with standardized dilution techniques, diffusion methods require the use of laboratory control microorganisms to control the technical aspects of the laboratory procedures. For the diffusion technique, the 5 mcg levofloxacin disk should provide the following zone diameters in these laboratory test quality control strains:

Microorganism		Zone diameter (mm)
Escherichia coli	ATCC 25922	29 - 37
Pseudomonas aeruginosa	ATCC 27853	19 - 26
Staphylococcus aureus	ATCC 25923	25 - 30
Haemophilus influenzae	ATCC 49247 ^g	32 - 40
Streptococcus pneumoniae	ATCC 49619 ^h	20 - 25

^g This quality control range is applicable to only *H. influenzae* ATCC 49247 tested by a disk diffusion procedure using Haemophilus Test Medium (HTM)^{*2}.

^h This quality control range is applicable to only *S. pneumoniae* ATCC 49619 tested by a disk diffusion procedure using Mueller-Hinton agar supplemented with 5% sheep blood and incubated in 5% CO₂.

TOXICOLOGY

The potential toxicity of levofloxacin has been evaluated in acute, sub-chronic, carcinogenicity, mutagenicity, reproduction and teratology, and special toxicity studies.

Acute Toxicity

Table 2.47- Summary of the acute toxicity studies				
STRAIN/	# ANIMAL/	ROUTE	LD ₅₀	SUMMARY TOXIC SIGNS
SPECIES	GROUP		mg/kg	
Mouse	M - 10	p.o.	1881	↓ locomotor activity, ptosis, respiratory depression,
	F - 10	-	1803	tremor, convulsion
Mouse	M - 10	p.o.	1943	↓ locomotor activity, ptosis, prostration, tremor,
		-		convulsion
Rat	M - 10	p.o.	1478	salivation, ptosis, \downarrow locomotor activity, tremor,
	F - 10	_	1507	convulsion, respiratory depression
Rat	M - 10	p.o.	1754	
Monkey	F - 2	p.o.	>250	soft stool, transient \downarrow platelet count and \uparrow bw at 250
		_		mg/kg, transient \uparrow bilirubin, \downarrow bw, and emesis at 500

Table 2.49- Summary of the acute toxicity studies

				mg/kg
Mouse	M - 10	i.v.	268	\downarrow locomotor activity, ptosis, abnormal posture,
	F - 10		323	tachypnea, convulsion, dyspnea
Mouse	M - 5	i.v.	244	symptoms prior to death: tachypnea, collapse,
				dyspnea, convulsions, respiratory arrest. In survivors, ↓ locomotor activity and collapse
Rat	M - 10	i.v.	423	\downarrow locomotor activity, prostration followed by
	F - 10		395	respiratory depression, tachypnea, dyspnea,
				convulsion, tremor, salivation
Dog	F - 2	i.v.	200	salivation, dyspnea, tonic and clonic convulsion,
				death from respiratory arrest at 200 mg/kg,
				lacrimation, vomiting, lethargy, and tremors. \uparrow RBC,
				WBC, ALT and ALP, and \downarrow P on Day 2. Values
				returned to normal by Day 8.
Monkey	F - 2	i.v.	>200	at 200 mg/kg - ptosis, vomiting, ↓ locomotor activity,
				prostration and anorexia, ketone urine, proteinuria, \downarrow
				glucose. Ptosis and emesis at 100 mg/kg

Signs of acute toxicity with metabolites (desmethyl and N-oxide) were similar to that of levofloxacin and were produced at doses significantly greater than would be encountered with therapeutic use.

Sub-Chronic Toxicity

Species,	Route,	Results
Age/Grp/No.,	Dosage,	
Sex/Grp	Duration	
Rat 4-6 wk old 4 grp 10 ♀ & 10 ♂/ grp	p.o. 0, 50, 200, 800 4 weeks	Lethality: No treatment-related deaths. Clin Obs: Salivation, body staining, transient pallor and hypothermia at 800 mg/kg. Transient \downarrow fc in treated \bigcirc and \downarrow bw gain during week 1 in \bigcirc at 800 mg/kg. Clin Path: \uparrow WBC due to \uparrow in lymphocytes at 800 mg/kg. PMNs \downarrow in treated \bigcirc and at 50 and 200 mg/kg in \bigcirc . \downarrow K+, Cl-, and urea and \uparrow P and ALT (primarily at 800 mg/kg). Higher M:E ratio at 800 mg/kg. Micro: \downarrow relative heart weights at 800 mg/kg and \uparrow cecal weights at 200 and 800 mg/kg. Slight vacuolization and minimal hypertrophy of hepatocytes at 800 mg/kg and arthropathy (minor) at 800 mg/kg. NOAEL = 200 mg/kg/day. TI = 2.8
Rat 4-5 wk old 4 grp 20 ♀ & 20 ♂/ grp	p.o. 0, 20, 80, 320 26 wk	Lethality: No treatment-related deaths. Clin Obs: Salivation, \uparrow large fecal pellets, and stained haircoat mainly at 320 mg/kg. \uparrow fc at 80 and 320 mg/kg, \uparrow food conversion ratios in \bigcirc at 320 mg/kg. Clin Path: \downarrow PMNs in all treated rats, \uparrow glucose (treated \eth), \downarrow triglycerides (320 mg/kg \bigcirc), \downarrow β -globulin (treated rats), $\downarrow \alpha$ - globulin (treated \bigcirc), \downarrow Cl- (320 mg/kg rats and 80 mg/kg \bigcirc), \downarrow total protein (80 and 320 mg/kg \circlearrowright), and \uparrow urinary pH at 80 and 320 mg/kg. Micro: Dosage-related \uparrow cecal weight, elongated and/or distended ceca and engorged goblet cells of the cecal mucosa. Changes in intestinal flora and lower nutrient absorption in the intestines probably responsible for most changes. No arthropathy. NOAEL = 20 mg/kg/day. TI = 2.8

 Table 2.50 - Summary of the sub-chronic toxicity studies

Species,	Route,	Results
Age/Grp/No.,	Dosage,	
Sex/Grp	Duration	
Rat	diet	Lethality: No deaths. Clin. Obs: \downarrow bw at 400 and 800 mg/kg. Clin
6 wk old	0, 100, 200,	Path : ↓ total protein (≥200 mg/kg), globulin, and triglycerides (at
5 grp	400, 800	800 mg/kg $\stackrel{\frown}{\odot}$ only). \uparrow ALP at 800 mg/kg ($\stackrel{\bigcirc}{\ominus}$). Micro: \downarrow absolute
10 ♀ & 10 ♂/ grp	13 wk	liver weight ≥ 400 (Å), \uparrow cecal weight and cecal distension (≥ 100).
		No arthropathy. NOAEL = 100 mg/kg/day. TI = 14

Carcinogenicity

Levofloxacin exhibited no carcinogenic or tumorigenic potential after dietary administration of 10, 30 or 100 mg/kg/day for 2 years in a rat carcinogenicity study. The highest dose was 1.4 or 6.7 times the highest recommended human dose (750 mg) based on surface area or body weight, respectively. The mean levofloxacin plasma concentration in the 2-year rat bioassay (at 100 mg/kg/day) was 34% of the human steady-state concentration after 500 mg b.i.d. dosing. In a 2-stage multiple organ carcinogenesis model in rats, levofloxacin at a dosage level of approximately 668 mg/kg/day in diet for 16 weeks did not promote the development of preneoplastic or neoplastic lesions after pretreatment with a number of wide spectrum carcinogens.

Mutagenicity

Levofloxacin was not mutagenic in the following assays: Ames bacterial mutation assays (S. typhimurium and E. coli), CHO/HGPRT forward mutation assay, mouse micronucleus test, mouse dominant lethal test, rat unscheduled DNA synthesis and the mouse sister chromatid exchange (SCE) assays. It was positive in the in vitro chromosomal aberration (CHL cell line) and SCE assays (CHL/IU cell line).

Special Studies

Arthropathic Potential

Levofloxacin and other quinolones have been shown to cause arthropathy in immature animals of most species tested (see **WARNINGS AND PRECAUTIONS**). In juvenile rats, 7 days of oral administration of 300 mg/kg/day levofloxacin results in blister and cavity formation in articular cartilage. In juvenile dogs (4 months old), 7 days of oral administration of 10 mg/kg/day levofloxacin produces blister formation, cavitation, and increased synovial fluid of diarthroidal joints. In young immature dogs (13 months old), blister formation and cavitation of the arthritic joint were observed in 1/3 dogs following oral administration of 40 mg/kg/day levofloxacin for 7 days.

In long-term multidose studies, arthropathy in rats was observed after oral administration of 800 mg/kg/day for 4 weeks, after intravenous administration at 60 mg/kg/day for 4 weeks and 90 mg/kg/day for 13 weeks. Arthropathic lesions were observed in 4-month-old dogs following 4 mg/kg/day intravenous administration for 2 weeks and in 7-8-month-old dogs following 10 mg/kg/day intravenous administration for 4 weeks. No arthropathy was observed following 2-week intravenous dosing at dosages up to 30 mg/kg/day in young adult dogs (18 months old).

Three-month old beagle dogs dosed orally with up to 40 mg/kg/day levofloxacin for 8 or 9 consecutive days, with an 18-week recovery period, exhibited musculoskeletal clinical signs by the final dose at dose levels ≥ 2.5 mg/kg (approximately 0.2-fold the pediatric dose based upon AUC comparisons). Synovitis and articular cartilage lesions were observed at the 10 and 40 mg/kg dose levels (equivalent to and 3-fold greater than the potential therapeutic dose, respectively). All musculoskeletal clinical signs were resolved by week 5 of recovery; synovitis was resolved by the end of the 18-week recovery period; whereas, articular cartilage erosions and chondropathy persisted.

Phototoxicity

When tested in a mouse ear swelling bioassay, levofloxacin exhibited phototoxicity similar in magnitude to ofloxacin but less phototoxicity than some of the other quinolones tested. A single oral administration of 800 mg/kg levofloxacin followed by UVA exposure has been shown to result in ear erythema and swelling.

Crystalluria

When tested in rats with 20, 60, 120 or 180 mg/kg of levofloxacin, crystalluria has been observed in some intravenous rat studies; urinary crystals are not formed in the bladder, being present only after micturition and are not associated with nephrotoxicity.

Cardiac Effects

Levofloxacin exhibits a weak interaction with the human HERG channel. The IC50 for levofloxacin in inhibiting human HERG K+ channel is 915 mcM. At therapeutic doses of 250, 500, and 750 mg levofloxacin, the peak unbound plasma concentrations ranged from 6 mcM for a single oral levofloxacin dose of 250 mg to 12 mcM and 15 mcM for 500 and 750 mg levofloxacin doses, respectively.

Studies in rabbit Purkinje fibers and studies in guinea pig right ventricular myocardium revealed no detectable effect on action potential duration with levofloxacin at concentrations up to 100 mcM.

The potential for levofloxacin to induce torsades de pointes was examined in a canine model of chronic high-degree atrioventricular block. Oral administration of levofloxacin at 6 and 60 mg/kg induced no ventricular arrhythmias. Monophasic action potential duration (MAP₉₀) was not significantly affected by levofloxacin 0.3 and 3.0 mg/kg IV.

PART III: CONSUMER INFORMATION

^{Pr}Levofloxacin in 5% Dextrose Injection

This leaflet is Part III of a three-part "Product Monograph" published when Levofloxacin in 5% Dextrose Injection was approved for sale in Canada and is designed specifically for Consumers. This leaflet is a summary and will not tell you everything about Levofloxacin in 5% Dextrose Injection. Contact your doctor or pharmacist if you have any questions about the drug.

Before you start to take your medicine, please read this leaflet carefully, all the way through, as it contains important information.

Retain this leaflet for the duration of your treatment.

Remember to consult your doctor if you feel that Levofloxacin in 5% Dextrose Injection is not helping you get better, or if you feel worse.

ABOUT THIS MEDICATION

What the medication is used for:

Levofloxacin in 5% Dextrose Injection is from a group of antibiotics known as quinolones. Levofloxacin in 5% Dextrose Injection is used to treat adults with certain lung, sinus, skin and urinary tract infections caused by certain germs called bacteria.

What it does:

Levofloxacin in 5% Dextrose Injection has been shown, in a large number of clinical trials, to be effective for the treatment of bacterial infections. Levofloxacin in 5% Dextrose Injection interferes with bacterial enzymes to prevent bacterial growth, thereby killing many types of bacteria that can infect the lungs, sinus, skin, and urinary tract.

Sometimes, viruses rather than bacteria may infect the lungs and sinuses (for example, the common cold). Levofloxacin in 5% Dextrose Injection, like other antibiotics, does not kill viruses.

When it should not be used:

You should not take Levofloxacin in 5% Dextrose Injection if you have had an allergic reaction to any of the group of antibiotics known as quinolones, or to any of the nonmedicinal ingredients (see **What the nonmedicinal ingredients are**). This includes antibiotics such as ofloxacin, ciprofloxacin, moxifloxacin hydrochloride, gatifloxacin and norfloxacin. If you have had any reaction to quinolones, you should discuss this with your doctor.

You should not take Levofloxacin in 5% Dextrose Injection if you have had tendinitis or tendon rupture while taking quinolone antibiotics.

What the medicinal ingredient is:

Levofloxacin in 5% Dextrose Injection contains the active (medicinal) ingredient levofloxacin.

What the important nonmedicinal ingredients are:

Dextrose, water for injection Solutions of hydrochloric acid and/or sodium hydroxide may have been added to adjust the pH.

What dosage forms it comes in:

Levofloxacin in 5% Dextrose Injection is supplied in single-use flexible containers containing a premixed, ready-to-use levofloxacin solution in D₅W in the following formats:

- Containers of 100 mL capacity containing 50 or 100 mL of premixed solution.
- Containers of 250 mL capacity containing 150 mL of premixed solution.

WARNINGS AND PRECAUTIONS

Serious Warnings and Precautions

- Levofloxacin has been shown to lengthen the heartbeat on an electrocardiogram test (QT interval prolongation).
- Serious hypersensitivity (allergic) reactions, sometimes fatal, have been reported in some patients receiving quinolone therapy, including levofloxacin.
- Fluoroquinolones, including Levofloxacin, may worsen muscle weakness in persons with myasthenia gravis. Do not use Levofloxacin in 5% Dextrose Injection if you have or have had myasthenia gravis.
- Fluoroquinolones, including Levofloxacin, are associated with disabling and long lasting effects such as:
 - tendonitis (inflamed tendon), tendon rupture
 - peripheral neuropathy (problems in the nerves)
 - problems in the brain such as seizures, psychoses, confusion and other symptoms

See **SIDE EFFECTS AND WHAT TO DO ABOUT THEM** of the Consumer Information section for further information on symptoms.

Talk to your doctor to see if this medication is suitable for you.

BEFORE you use Levofloxacin in 5% Dextrose Injection talk to your doctor or pharmacist if:

- you have an aortic aneurysm, which is an abnormal bulge in a large blood vessel called the aorta
- you have or if anyone in your family has a condition called aneurysm disease, which is an abnormal bulge in any large blood vessel in the body
- you have an aortic dissection, which is a tear in the wall of the aorta
- you have any of the following conditions: Marfan syndrome, vascular Ehlers-Danlos syndrome, Takayasu arteritis, giant cell arteritis or Behcet's disease

- you have high blood pressure
- you have atherosclerosis, which is a hardening of your blood vessels
- you have decreased kidney function
- you have a history of seizures
- you have a history of tendon problems associated with the use of quinolone antibiotics
- you have had any problems with your heart rhythm, heart rate, or problems with low potassium
- you are taking anti-diabetic medications as Levofloxacin in 5% Dextrose Injection may interfere with blood sugar levels
- you have a disease that causes muscle weakness (myasthenia gravis)
- you experience any symptoms of muscle weakness, including breathing difficulties (e.g., shortness of breath).

Other Warnings:

Because Levofloxacin in 5% Dextrose Injection only works on certain types of bacteria, you can develop an infection from another type of bacteria that Levofloxacin in 5% Dextrose Injection doesn't treat (resistant bacteria). Talk to your doctor if your infection gets worse while taking Levofloxacin in 5% Dextrose Injection.

INTERACTIONS WITH THIS MEDICATION

Before taking Levofloxacin in 5% Dextrose Injection, make sure you tell your doctor and pharmacist all the medications you are taking. Do not start a new medicine without first consulting a doctor or pharmacist.

It is important to let your doctor know all of the medicines you are using including some medications for arthritis (non-steroidal antiinflammatory drugs), blood sugar medicines, drugs for any heart condition, and non-prescription drugs, because Levofloxacin in 5% Dextrose Injection may react with certain medications.

Taking warfarin and Levofloxacin in 5% Dextrose Injection together can further predispose you to the development of bleeding problems. If you take warfarin, be sure to tell your doctor.

Many multi-vitamin/mineral combinations and antacids, containing calcium, magnesium, aluminum, iron, zinc and sucralfate may interfere with the absorption of Levofloxacin in 5% Dextrose Injection and may prevent it from working properly. You should take Levofloxacin in 5% Dextrose Injection either two hours before or two hours after taking these products.

Some medicines such as erythromycin, clarithromycin, quinidine, procainamide, amiodarone, sotalol, cisapride*, antipsychotics, tricyclic antidepressants, and other medications may produce an effect on the electrocardiogram test. The risk of developing abnormal heartbeat may be increased when Levofloxacin in 5% Dextrose Injection is taken with any of these medications. Do not take any of these medications with Levofloxacin in 5% Dextrose Injection unless your doctor tells you that it is alright. Levofloxacin in 5% Dextrose Injection may affect the results of tuberculosis tests. Tell your healthcare professional that you are taking Levofloxacin in 5% Dextrose Injection if you are being tested for tuberculosis.

* No longer marketed in Canada

PROPER USE OF THIS MEDICATION

Usual dose:

Levofloxacin in 5% Dextrose Injection is to be administered intravenously.

You may begin to feel better quickly; however, in order to make sure that you are getting the full, sustained benefits from your medication so that your infection does not return, you **should complete the full course of medication.**

Overdose:

In case of drug overdose, contact a health care practitioner (e.g., doctor), hospital emergency department or regional Poison Control Centre immediately, even if there are no symptoms.

Missed Dose:

Do not take more than the prescribed dose of Levofloxacin in 5% Dextrose Injection even if you missed a dose by mistake. You should not take a double dose.

Antibacterial drugs like Levofloxacin in 5% Dextrose Injection treat <u>only</u> bacterial infections. They do not treat viral infections such as the common cold. Although you may feel better early in treatment, Levofloxacin in 5% Dextrose Injection should be used exactly as directed. Misuse or overuse of Levofloxacin in 5% Dextrose Injection could lead to the growth of bacteria that will not be killed by Levofloxacin in 5% Dextrose Injection (resistance). This means that Levofloxacin in 5% Dextrose Injection may not work for you in the future. Do not share your medicine.

SIDE EFFECTS AND WHAT TO DO ABOUT THEM

What are possible side effects from using Levofloxacin in 5% Dextrose Injection?

Self-Limiting Side Effects

- Feeling lightheaded
- Insomnia (difficulty sleeping)
- Nightmares

Levofloxacin is generally well tolerated. The most common side effects caused by levofloxacin which are usually mild, include nausea, vomiting, diarrhea, abdominal pain, constipation, dizziness, flatulence, rash, headache, difficulty in sleeping, and vaginitis in women. However, allergic reactions have been reported in patients receiving quinolones, including levofloxacin, even after just one dose. If you develop hives, itching, skin rash, difficulty breathing or swallowing, swelling in the face, tongue or throat, or other symptoms of an allergic reaction, you should stop taking this medication and call your doctor.

Levofloxacin may be associated with dizziness. You should know how you react to this drug before you operate an automobile, or machinery, or perform other activities requiring mental alertness or co-ordination.

Convulsions have been reported in patients receiving quinolone antibiotics including levofloxacin. If you have experienced convulsions in the past, be sure to let your physician know that you have a history of convulsions.

Fluoroquinolones, including levofloxacin, have been rarely associated with inflammation of the tendons. Pain, swelling and tears of shoulder, hand, or Achilles tendons have been reported in patients receiving quinolones, including levofloxacin. The risk of tendon effects is higher if you are over 60 years old, and especially if you are taking corticosteroids. If you experience pain, swelling, or rupture of a tendon you should:

- stop taking levofloxacin
- rest
- avoid physical exercise
- call your health care professional.

Fluoroquinolones, including levofloxacin, have been rarely associated with effects such as:

- confusion, tremors, headache,
- *hallucinations, depression, agitation,*
- insomnia, anxiety, nervousness and suicidal thoughts.

If you have suicidal thoughts, contact your doctor. Neuropathy (problems in the nerves) has been reported in patients receiving quinolones, including levofloxacin. If neuropathy symptoms occur such as pain, burning, tingling, numbness, or weakness, you should:

- stop taking levofloxacin
- *contact your doctor immediately.*

Sun sensitivity (photosensitivity), which can appear as skin eruption or severe sunburn, can occur in some patients taking quinolone antibiotics after exposure to sunlight or artificial ultraviolet (UV) light (e.g., tanning beds). Levofloxacin has been infrequently associated with phototoxicity. You should avoid excessive exposure to sunlight or artificial ultraviolet light while you are taking Levofloxacin in 5% Dextrose Injection. Use sunscreen and wear protective clothing if out in the sun. If photosensitivity develops, contact your doctor.

Blood Sugar Changes

Medicines like Levofloxacin in 5% Dextrose Injection can cause blood sugar levels to rise and drop in patients with diabetes. Serious cases of <u>hypoglycemia</u> (low blood sugar levels) that caused coma or death have been seen with medicines like Levofloxacin in 5% Dextrose Injection. If you have diabetes, check your blood sugar levels often while taking Levofloxacin in 5% Dextrose Injection. Hyperglycemic and hypoglycemic (high and low blood sugar respectively) reactions have also been reported in patients without diabetes. Common symptoms of hyperglycemia (high blood sugar) include excessive thirst or excessive urination. Common symptoms of hypoglycemia (low blood sugar) include dizziness, excessive hunger, lack of coordination, headache, fatigue, or fainting. You should call your doctor if you experience any of these symptoms.

Problems with the liver, including fatal cases, have been reported in patients taking levofloxacin. The symptoms of hepatic impairment are non-specific and include nausea, vomiting, stomach pain, fever, weakness, abdominal pain or tenderness, loss of appetite, itching, unusual or unexplained tiredness, light coloured bowel movements and dark coloured urine. In more severe cases, these symptoms are followed by jaundice (yellowing of the skin) and/or icterus (yellowing of the eyes). Call your doctor if you experience these symptoms.

Some quinolones have been associated with lengthening of the heartbeat on an electrocardiogram test, and with abnormal heart rhythm. Very rare cases of abnormal heart beat have been reported in patients while on levofloxacin, but these reports generally involved patients who had conditions that predisposed them to abnormal heart beat, or who have been taking other medicines that increase the risk of developing abnormal heartbeat. If you develop heart palpitations (fast beating) or have fainting spells, you should stop taking Levofloxacin in 5% Dextrose Injection and call your doctor.

Eye abnormalities and abnormal vision have been reported in patients being treated with quinolones. The relationship of the drugs to these events has not been established.

Diarrhea that usually ends after treatment is a common problem caused by antibiotics. A more serious form of diarrhea can occur during or up to 2 months after the use of antibiotics. This has been reported with all antibiotics, including with levofloxacin. If you develop a watery and bloody stool with or without stomach cramps and fever, contact your doctor as soon as possible.

Fluoroquinolones like Levofloxacin may cause worsening of myasthenia gravis symptoms, including muscle weakness and breathing problems. If you have or have had myasthenia gravis, do not use Levofloxacin in 5% Dextrose Injection.

These are not all the side effects that have been reported with levofloxacin. If you notice any side effects not mentioned in this leaflet, or you have concerns about the side effects you are experiencing, please inform your doctor.

HOW TO STORE IT

Levofloxacin in 5% Dextrose Injection should be stored at 15- 30° C.

Avoid excessive heat and protect from freezing and light. Store with protective overwrap and use immediately once removed from the overwrap.

REPORTING SUSPECTED SIDE EFFECTS

You can report any suspected side effects associated with the use of health products to Health Canada by:

- Visiting the Web page on Adverse Reaction Reporting (https://www.canada.ca/en/health-canada/services/drugs-health-products/medeffect-canada/adverse-reaction-reporting.html) for information on how to report online, by mail or by fax; or
- Calling toll-free at 1-866-234-2345

NOTE: Contact your health professional if you need information about how to manage your side effects. The Canada Vigilance Program does not provide medical advice.
